TITLE PAGE

THE BIOCHEMICAL EFFECTS OF *CUSSONIA ARBOREA* ROOT BARK EXTRACT IN ALLOXAN-INDUCED DIABETIC RATS

BY

ABA, PATRICK EMEKA
DVM, MSc (UNN)
PG/PhD/11/58702

THESIS SUBMITTED TO THE DEPARTMENT OF VETERINARY PHYSIOLOGY AND PHARMACOLOGY, FACULTY OF VETERINARY MEDICINE, UNIVERSITY OF NIGERIA, NSUKKA FOR THE AWARD OF THE DEGREE OF DOCTOR OF PHILOSOPHY

NOVEMBER, 2015

CERTIFICATION

ABA, PATRICK EMEKA, a postgraduate student in the Department of Veterinary Physiology and Pharmacology, with registration number PG/PhD/11/58702 has satisfactorily completed the requirements for the degree of Doctor of Philosophy in Veterinary Biochemistry.

The work embodied in this thesis is original and has not been submitted in part or full for any diploma or degree of this or any other University.

PROF. I.U ASUZU	**PROF. S.C UDEM**
(SUPERVISOR)	**(HEAD OF DEPARTMENT)**
PROF. B.M AGAIE	**PROF. C.O NWOSU**
(EXTERNAL EXAMINER)	**(DEAN, FACULTY OF VETERINARY MEDICINE)**

DEDICATION

TO GOD ALMIGHTY BE ALL THE GLORY

ACKNOWLEDGEMENTS

My first line of appreciation goes to God Almighty, the author and finisher of my life. His loving kindness in my life is unending. I bless His name.

I equally wish to announce my unreserved appreciation to my family members- my lovely wife, beautiful daughter, caring mother, wonderful sisters and great in-laws for the encouragement I received from them during this study. I sincerely appreciate them.

One of my most important unadulterated, effusive and profound gratitudes goes to my supervisor, Professor I.U ASUZU, the Vice Chancellor of Federal University, Oye-Ekiti, Ekiti state, who equally doubles as my role model and mentor. I thank him not only as my supervisor whose emulative qualities are unparalleled but as a father, spiritual motivator, morale booster, friend and above all, for being highly instrumental for whatever I have become today in my life. I owe all to his instrumentality. Despite his tight schedules as the Vice Chancellor, he still has time to meticulously and timely attend to my needs. Many a time, I feel words are not enough to say THANK YOU. However, gold and silver I have not; I just wish to say THANK YOU and may God Almighty continue to shower you with His blessings.

This acknowledgement would be grossly inadequate if I fail to appreciate the sincere aid rendered to me in the course of this onerous task by the following members of staff- Prof. S.C Udem (Head of Department), Prof. J.I Ihedioha (Director of Veterinary Hospital), Prof. P.A Onyeyili, Prof. S.M Anika, Prof. C.N Uchendu, Prof. A.O Anaga, Prof. I.R Obidike, Prof. I.I Madubunyi, Prof. R.C Ezeokonkwo, Dr. L.O Aka. Also worthy of mention are my research fellows- Dr. V.U Omoja, Dr.(Mrs) R.I Odo, Dr. I.G Eke, Dr. I.K Idika, Dr. C.O Okorie-Kanu, Dr. J. Bosha, Dr. E.C Mbegbu, Dr.(Mrs) T.E Ihedioha, Dr.(Mrs), C.O Nwaigwe, Mrs V. Madu,

Mrs. M.C Onu, Miss Odinaka and other members of staff of the Department of Veterinary Physiology and Pharmacology (VPP) to mention only but a few.

Lastly but definitely not the least, I wish to heartily recognize the professional and technical assistance of Dr. J. Igoli of the University of Strathchyde, Glasgow , Scotland, UK, Prof. P.O Ukoha, of Chemistry Department and Dean Faculty of Physical sciences, Mr. E Mbaoji of the Department of Chemistry and Mr A. O Ozioko formally of Plant Science Department. Thank you all.

ABSTRACT

Diabetes mellitus is a group of metabolic disorders characterized by chronic hyperglycemic condition resulting from defects in insulin secretion, insulin action or both. It is a growing public health concern worldwide affecting humans and animals. Synthetic drugs available for the treatment of the ailment have serious side effects, complicated mode of intake and are costly. Literature search revealed that *Cussonia arborea* is used folklorically in the management of Diabetes mellitus. The aim of this study is to isolate, characterize and elucidate the active principle responsible for its hypoglycaemic activity using alloxan-induced diabetic rats. The root bark of *C. arborea* (2 kg) was extracted with 80% methanol by cold maceration method. Acute toxicity study was done in 35 rats assigned into 7 groups of 5 rats per group. Groups 1, 2,3,4,5 and 6 rats were orally administered with graded doses (500, 1000, 2000, 3000, 4000, 5000 mg/kg bw) of the extract respectively. The rats in group 7 received 10 ml/kg distilled water (DW) to serve as negative control group. They were observed closely for 48 hours for signs of toxicity. Assessment of hypoglycemic activities of the extract was done using oral glucose tolerance test (OGTT), acute and chronic antidiabetic studies. In OGTT, 30 rats were randomly assigned into 5 groups of six rats per group. Groups 1, 2 and 3 rats received 250, 500 and 1000 mg/kg bw of the extract respectively while groups 4 and 5 rats received 2 mg/kg bw glibenclamide and 10 ml/kg DW respectively after 18 h fasting and prior to 2000 mg/kg of glucose load. The fasting blood glucose (FBG) levels of the rats were determined after 30, 60, 120 and 180 min post glucose challenge. Diabetes was induced by single intraperitoneal administration of alloxan monohydrate at the dose of 160 mg/kg bw. Rats with FBG levels above 126 mg/dl (7 mMol/L) were considered diabetic. Thirty male albino Wistar rats assigned into 6 groups of 5 rats per group were used for acute antidiabetic studies. Groups 1, 2, 3, 4 and 5 were diabetic rats treated with 250, 500 1000 mg/kg bw of the extract, 2 mg/kg bw glibenclamide and 10 ml/kg DW respectively while group 6 rats were non diabetic but administered with 10 ml/kg DW. The FBG levels of the rats were determined 1 h, 3 h, 6 h and 24 h post treatment. Seventy two (72) male albino wistar rats weighing between 100 and 105 g were assigned into six groups of 12 rats per group for chronic antidiabetic studies. Groups 1, 2, 3, 4 and 5 rats were made diabetic as described earlier and treated with 62.5, 125, 250 mg/kg bw of the extracts, 2 mg/kg bw glibenclamide and 10 ml/kg DW respectively while the non diabetic group 6 rats received 10 ml/kg DW and served as normal control rats. The treatment was daily through the oral route for

84 days. The biochemical (aspartate aminotransferase (AST), alanine aminotransferase (ALT), total cholesterol, triglyceride, high density lipoprotein (HDL), very low density lipoprotein (VLDL), low density lipoprotein (LDL), total protein, albumin, globulin, blood urea nitrogen, creatinine, total bilirubin, conjugated bilirubin, unconjugated bilirubin, malondiadehyde (MDA), superoxide dismutase (SOD), catalase, and reduced glutathione) and haematological (red blood cell (RBC), haemoglobin (Hb), packed cell volume (PCV), white blood cell (WBC), differential leucocytes (lymphocytes, neutrophils, basophils, eosinophils and monocytes), mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH), mean corpuscular haemoglobin concentration (MCHC)) parameters were assayed on days 28, 56 and 84 post treatment while the FBG values and weight changes were determined every two weeks. The glycosylated haemoglobin values were measured on days 42, 56 and 84 post treatment. Three rats per group were humanly sacrificed on days 28, 56 and 84 for the assessment of the histomorphology of various organs (pancreas, kidney, liver and heart). *In vitro* antioxidant assay was carried out using ferric reducing antioxidant power (FRAP) and diphenyl picryl hydrazyl (DPPH) photometric assay models. Chromatographic separation of the plant extract was done using column and thin layer chromatographic techniques. The ^{1}H proton and ^{13}carbon nuclear magnetic resonance (NMR) were used for structural elucidation of the active hypoglycaemic principle. No sign of toxicity was observed after acute toxicity test. The phytochemical analysis revealed the presence of alkaloids, flavonoids, glycosides, saponins, tannins and terpenes. The mean FBG level of the rats treated with 250 mg/kg bw of the extract in acute anti-diabetic study, at 3 h post extract administration was significantly ($p<0.05$) lower than the FBG before administration of the extract. In the chronic anti-diabetic study, the mean FBG level of rats treated with 125 mg/kg bw of the extract reduced significantly ($p<0.05$), the post induction FBG from 315.33± 10.08 mg/dl to 93.00 ±8.50 mg/dl, 14 days post administration and ameliorated the glycosylation of haemoglobin compared to the negative control group. Administration of 250 mg/kg bw of the extract in glucose challenged rats reduced the post challenge glucose level from 147.66 ±1.85 mg/dl to 83.00 ±3.5 mg/dl, 180 min post treatment. Assessment of the biochemical and haematological parameters in chronically-treated diabetic rats showed that the administration of 125 mg/kg bw of the extract, significantly ($p<0.05$) reduced the activities of AST, ALT and the levels of total cholesterol, triglyceride, VLDL, LDL BUN, creatinine, total bilirubin, malondialdehyde but significantly ($p<0.05$) increased the activities of SOD, catalase and the

levels of HDL, total protein, conjugated bilirubin, reduced glutathione , RBC, Hb and PCV when compared to the diabetic untreated group (negative control). The extract yielded seven fractions. The FBG of the rats treated with 12.5 mg/kg bw of fraction 2 was significantly ($p<0.05$) lower compared to the negative control group. Subfraction 1 (2 mg/kg) of fraction 2 significantly ($p<0.05$) reduced the FBG levels from 310.00±5.77 mg/dl to 74.00±0.57 mg/dl. Rats treated with 125 mg/kg bw of the extract showed milder histopathologic lesions in various tissues compared with negative control. The DPPH *in vitro* antioxidant assay showed a concentration dependent activities with 400 µg/ml of the extract and ascorbic acid showing 74% and 92% activities respectively. The FRAP values of the extract and ascorbic acid at 400µg/ml were 1.60 and 2µm respectively. The NMR spectroscopy revealed a pentacyclic triterpenoid, {(3ϐ)-3-hydroxyolean-12-en-28-oic acid} as the active compound. The study showed that the root bark extract of *C. arborea* did not only possess antihyperglycaemic, hypolipidemic, antioxidant and antianemic properties but also reduced haemoglobin glycosylation and ameliorated the severe degenerative lesions in the pancreas, kidney, liver and cardiac myocytes occasioned by *Diabetes mellitus*.

`CHAPTER ONE

INTRODUCTION

Diabetes is a complex and a multifarious group of metabolic disorders that disturbs the metabolism of carbohydrates, fats and protein (Kahn and Shechter, 1991**;** Bliss, 2000). It is characterized by increased fasting and postprandial blood glucose levels. *Diabetes mellitus* is a group of metabolic disorder resulting from defects in insulin secretion or reduced sensitivity of the tissues to insulin action or both (Lanza *et al.,* 2001). It is a disease characterized by inability to regulate blood glucose as a result of relative or absolute deficiency in insulin. This results to hyperglycemia often accompanied by glycosuria, polydipsia and polyuria (Celik *et al.,*2002) Besides hyperglycaemia, several other factors like hyperlipidaemia and enhanced oxidative stress play a major role in diabetes pathogenesis. The disease is progressive and is associated with high risk of complication (Dewanjee *et al.,* 2008). It is one of the most common endocrine diseases and has a prevalence rate varying from 1- 50% (King and Rewers, 1993**).**

The term ñ*Diabetes Mellitus*ò is derived from the Greek words dia (through), bainein (to go) and diabetes literally means pass through. The disease causes loss of weight as if the body mass is passed through the urine. Although it was known for centuries that the urine of patients with diabetes was sweet, it was not until 1674 that the physician named Willis coined the term *Diabetes mellitus* (from the Greek word for honey) (Vasudevan and Kumari, 2005).

Although many types of *Diabetes mellitus* exist (Tierney *et al*, 2002), it has been broadly classified into two by World Health Organization (WHO, 1980). Type I diabetes mellitus ï insulin dependent *Diabetes mellitus* and type 2 *Diabetes mellitus*-Non insulin dependent *Diabetes mellitus*. Type 1 *Diabetes mellitus* is characterized by loss of the insulin-producing beta cells of the islet of langerhans in the pancreas, leading to insulin deficiency. This type can be

further classified as immune-mediated or idiopathic. The majority of type 1 diabetes is of the immune-mediated nature, in which beta cell loss is a T-cell-mediated auto immune attack (Rother, 2007) Type 2 *Diabetes mellitus* is characterized by insulin resistance which may be combined with relatively reduced insulin secretion (Shoback, 2011). Type 2 diabetes is the most common type. Other forms of diabetes that have been described include Gestational diabetes mellitus, type 3 diabetes mellitus (Alzeibers disease) and non specific types (Shoback, 2011). Gestational *Diabetes mellitus* (GDM) is a third major category of diabetes. It occurs in at least 5 to 14 percent of pregnancies. It may improve or disappear after delivery (Cousens, 2008). Alzheimerôs disease has a strong connection with diabetes, obesity and heart disease. It is such strong connection that Alzheimerôs is being referred to by some scientists as type 3 diabetes (Rivera *et al*., 2005). Alzeheimerôs disease is a chronic neuro-degenerative disease that usually starts slowly and gets worse over time (Burns and Lliffe, 2009). The most common early symptom is difficulty in remembering recent events (Short term memory loss) (Burns and LLiffe, 2009). Mental and physical exercise and avoiding obesity may decrease the risk of Alzheimers disease (Ballard *et al*., 2011).

Other specific types of *Diabetes mellitus* include Latent autoimmune diabetes of adults (LADA) which is a condition in which type 1 *Diabetes mellitus* develops in adults. Adults with LADA are frequently initially misdiagnosed as having type 2 DM based on age rather than etiology. Genetic mutations (autosomal or mitochrondrial) can lead to defects in beta cell function. Any disease that can cause extensive damage to the pancreas may lead to diabetes (for example chronic pancreatitis and cystic fibrosis). Diseases associated with excessive secretion of insulin-antagonistic hormones can cause diabetes (which is typically resolved once the hormone

excess is removed). Many drugs impair insulin secretion and some toxins damage pancreatic beta cells (WHO, 1999).

The incidence of *Diabetes mellitus* in dogs and cats has been noted. Middle to older dogs and cats are mainly affected. Females are affected twice as often as males and the incidence appears to be increased in certain small breeds such as chow chow, Alashan Malamute, poorly (Kahn, 2005). *Diabetes mellitus* affects 1 in 400 (0.25%) cats through recent studies. Mc Cann *et al.,* (2007) noted that it is becoming more common lately in cats. The prevalence of diabetes mellitus in world population is increasing in epidemic proportion. In 1995, it was estimated that around 135 million people were affected by this condition and it was expected to affect 200 million by the year 2015 (King *et al.,* 1998). The World Health Organization warns that deaths due to diabetes will increase globally by as much as 80 percent in some regions over the next 10 years (WHO, 2005).

Common clinical signs of diabetes in dogs include polydipsia, polyuria, polyphagia with weight loss, bilateral cataract and weakness (Kahn, 2005). In cats the back legs may become weak and the gait may become stilted or wobbly consequent upon peripheral neuropathy. Untreated, the condition leads to increasingly weak legs in cats and eventually mal-nutrition, ketoacidosis and or dehydration and death but prompt effective treatment can lead to diabetic remission (Rand and Marshal, 2005). There are two forms of complications-acute and chronic complications. Diabetic Ketoacidosis (DKA) is one of the acute complications. Elevated levels of ketone bodies in the blood decrease the blood pH leading to DKA with classical signs of abdominal pains, lethargy, coma, hypotension, shock and death. Urine analysis will reveal significant levels of Ketone bodies (which appear in the urine after exceeding its renal threshold) (Aiello, 1998). Another acute complication is hyperglycemic hypoosmolar state in which water

will osmotically be withdrawn from the cells of a patient with very high blood sugar level, into the blood causing dehydration and increase in blood osmolarlity (Meyes, 2000).

Respiratory infection is another acute complication. The immune response is impaired in individuals with diabetes mellitus. Cellular studies have shown that hyperglycemia both reduces the function of immune cells and increases inflammation. The vascular effects of diabetes also tend to alter lung function which leads to an increase in susceptibility to respiratory infections such as pneumonia and influenza among individuals with diabetes. Several studies show that diabetes is associated with slower recovery from respiratory infection (Ahmed *et al.,* 2008).

All forms of diabetes increase the risk of long term complications. The major long term complications are relative to blood vessel damage (Boussageon *et al.,* 2011). The damage to small blood vessels leads to microangiopathy which has been incriminated in other chronic complications such as diabetic retinopathy, diabetic neuropathy, diabetic nephropathy and diabetic cardiomyopathy, while damage to the large vessels (Macrovascular disease) is sequel to cardiovascular disease such as coronary artery disease, and diabetic myonecrosis (Muscle wasting) (Aristides *et al.,* 2007). Another chronic complication is diabetic encephalopathy in which there is increased cognitive decline and the risk of dementia observed in diabetics. Various mechanisms are proposed including alterations to vascular supply of the brain and the interaction of insulin with the brain itself (Gispen and Biessels, 2000).

The diagnosis of *Diabetes mellitus* is based on persistent fasting hyperglycemia and glycosurias. Assay of glycosylated haemoglobin and fructoseamine may also help to differentiate between *Diabetes mellitus* and stress-induced hyperglycemia (Goldstein *et al.,* 1984). Other aids to diagnosis include clinical signs such as polyruria and polydipsia accompanied by weight loss, vision changes and unexplained fatigue or by observation of diabetes associated disease such as

poor wound healing, heart attack, stroke neuropathy, foot ulcers, certain fungal infections or delivery of baby with macrosomia (Dewanjee *et al.,* 2008; Twari and Rao, 2002). The normal fasting blood sugar value in dogs and cats is between 7-20 mMol/L (Kahn, 2005). In humans, diagnosis of diabetes is by demonstration of fasting plasma glucose level at or above 126 mg/dl (7 mMol/L) or plasma glucose at or above 200 mg/dl (11./Mmol/l) 2 hours after oral glucose load as in glucose tolerance test (WHO, 1999). Glucose tolerance test is a confirmatory method for the diagnosis of diabetes (WHO 1999**)** and it is determined by evaluating the concentration of the blood glucose at specific intervals before and after oral or intravenous administration of a given quantity of glucose. Both oral and intravenous routes may be used in the dog, however, in ruminants; the intravenous method must be used since there is no blood glucose response to oral administration of carbohydrate (Nelson, 2000). Glucose is irreversibly bound to hemoglobin (termed glycoslylated hemoglobin or HbA_{1C}). An elevated glucose level of 6% or higher is considered abnormal by most laboratories (Weykamp and panders, 1994). Glycosylated hemoglobin is used as a treatment-tracking test reflecting average blood glucose levels over the preceeding 90 days (approximately) which is the average life span of the red blood cells which contain hemoglobin in most patients (Goldstein *et al.,* 1984).

Insulin sensitivity test and insulin assay using enzyme-linked immunosorbent assay (ELISA) method can be used to aid diagnosis of diabetes mellitus. In insulin sensitivity, about 0.2 units of insulin is administered to the patient followed by monitoring of the blood glucose level over an interval of some hours (2-3 hrs). The blood glucose level will be lowered in patients that have absolute deficiency or reduced insulin secretion or absolute lack of insulin secretion. There will be no significant decrease in patients that have insulin dysfunction or resistance (Guyton, 1996). Insulin assay is used to differentiate between type 1 and type2

diabetes. In type 1 diabetic patients, no insulin will be detected after the assay, but in a type 2 patient, insulin level may be normal, reduced or high (WHO, 2006).

Treatment and management involve a combination of weight reduction diet, insulin and possibly oral hypoglycemic compounds. In cats, the use of high protein, low carbohydrate diets and in dogs, diets that are high in fiber and complex carbohydrate are preferred (Kahn, 2005) Dietary control is the cornerstone in the treatment of diabetes, irrespective of the severity of the symptom (Nelson, 2000). The diet should be targeted towards reduction of body weight, blood glucose levels and maintenance of good health. The oral hypoglycemic agents lower blood glucose level by different mechanisms. Sulfonylureas such as glyburide, meglitinides (repaglinide) and D- phenylalanine derivatives increase insulin production from the pancreas. Biguanides such as metformin decrease glucose release from the liver while alpha-glucosidase inhibitors such as glucobay (acarbose) slow down absorption of sugar from the gut. Thiazolidinediones (TZD or glitazone) such as pioglitazone, increase glucose uptake by fat and muscle cells. Exanatide and DPP-4 inhibitors such as sitagliptin reduce appetite, increase insulin production from the pancreas and decrease glucose release from the liver at once (Blumer, 2010). The first generation sulfonylureas include tolbutamide, acetohexamide, tolazamide and chlorpropamide while the second generation includes glibenclamide (glyburide) glipizide and gliclizide. The second generation agents are more potent than the first. Some pancreatic insulin secretary capacity must exist for sulfonylurea to be effective in improving glycaemic control (Nelson 2000). Sulfonylurea is ineffective as the sole form of treatment for insulin-dependent *Diabetes mellitus* (IDDM) and has not been effective in diabetic dogs presumably because of the high incidence of IDDM in this species. Sulfonylurea has the side effect of hypoglyemia (commonly), vomiting, nausea and cholestatic jaundice (Rang *et al.,* 2003). The biguanides like

metformin are used in patients with type 2 *Diabetes mellitus*. The commonest unwanted side effects are dose-related gastro-intestinal disturbances such as diarrhoea, nausea and anorexia (Grandhipuran *et al.,* 2006). Lactic acidosis is rare but potentially fatally toxic and metformin should not be given to a patient with renal or hepatic disease (Figmognari-pastorelli and Incalzi, 2006). Acarbose, oral alpha glucosidase inhibitors have been used in cats at the dosage of 125-250 mg. The most common side effects of acarbose include increased flatulence, diarrhoea abdominal bloating and kidney tumors in long term use. In humans, combination of diets, exercise and weight loss with oral diabetic drugs and use of insulin have proved to be effective. Exercise plays important role in the management of hyperglycaemic conditions by helping to promote weight loss as well as elimination of the insulin resistance induced by obesity (Edward *et al.,* 1987). Exercise also exerts a glucose lowering effect by increasing the absorption of insulin from injection site, increasing blood flow to exercising muscles and stimulating translocation of glucose effect (Nelson, 2000). Life style modification such as smoking less, wearing diabetic shoes or taking drugs that will minimize blood pressure will help to reduce the development of cardiovascular disease (Adler *et al.,* 2000). Insulin replacement therapy is another aid in the management of diabetes mellitus. Insulin lowers the concentration of glucose in the blood by inhibiting hepatic glucose production and by stimulating uptake and metabolism of glucose by muscle and adipose tissue (Rang *et al.,* 2003). Insulin is the main stake in the treatment of virtually all IDDM patients in who there is absolute lack of insulin. It is also used in the NIDDM patient that does not respond well to diet, physical exercise and hypoglycaemic agent treatment (Anaga and Asuzu, 2010). Diabetic dogs are mainly treated by exogenous insulin administration due to high incidence of IDDM in them (Nelson, 2000). There is no practical cure at this time for type 1 diabetes. The only time type 1 diabetes mellitus is said to have been

cured is in a condition of kidney-pancreas transplant (Vinik *et al.,* 2004). This can be done when diabetic nephropathy has developed. A simultenous pancreas-kidney transplant is a promising solution showing similar or improved survival rates over a kidney transplant alone (Strata and Alloway, 1998). Still, they remain on long term immunosuppressive drugs and there is a possibility that the immune system will mount a host versus graft response against the transplanted organ (Vinik *et al*., 2004). Transplant of exogenous beta cells have been performed experimentally in both mice and humans, but this measure is not yet practical in regular clinical practice partly due to the limited number of beta cell donors. Like any other transplant, it has provoked an immune reaction and long term immunosuppressants have been needed to protect the transplanted tissue (Shapiro *et al.,* 2006). Stem cell research has also been suggested as a potential avenue for cure since it may permit the re-growth of islet cells which are genetically part of the treated individual, thus, perhaps eliminating the need for immunosuppresants (Vinik *et al.,* 2004). In a trial, researchers implanted diabetes type 1 patient with their own stem cells raised from their own bone marrow. The stem cell transplant led to an appreciable repopulation of functioning insulin-producing beta cells in the pancreas, so the patients became insulin free. Most of these patients became insulin independents for a mean period of 18 months (Couri *et al.,* 2008). At present time, autologous non-myeloblastic Hematopoietic Stem-Cell Transplantation (HSCT) remains the only treatment capable of reversing type 1 *Diabetes mellitus* in humans.

In type 2 *Diabetes mellitus* in human, a gastric by-pass surgery can normalize blood glucose levels in 80-100% of severely obese patients. This approach may be standard for people with type 2 *Diabetes mellitus* in the near future (Rubino and Gagner, 2002).

The use of plants in the treatment of ailments dates back to the prehistoric times. Herbalism is a traditional medicine or a folk medicine-practice based on the use of plant and

plant extracts (Akah *et al.,* 1998). Many plants synthesize substances that are useful for the maintenance of health in humans and other animals. Africa is endowed with many plants that can be used for medicinal purposes. In fact, out of the approximated 64000 plant species used in tropical Africa, more than 4000 are used as medicine plants (Akah *et al.,* 1998). A recent review article presents the profile plants with hypoglycaemic properties reported in literature from 1990 to 2000 and states that medicinal plants play an important role in the management of diabetes mellitus especially in the developing countries where resources are meager (Bnouham, 2006). The first use of anti-diabetic drugs was as herbal extracts used by Indians in the Amazon Basin for the treatment of type 2 diabetes and today promoted as vegetable insulin although not formally an insulin analog (Soumyanath, 2005).

Some of the traditional plant treatment for diabetes include but are not limited to *Agrimonia eupararia* (Agrimony), *Juniperus communis* (Junipe) *Allium sativum* (garlic) (Swant son *et al.,* 1990). Others include *Strophantus hispidus, Gongronema latifolia, Morinda lucida, Vernonia colorata, Viscum album, Garcinia cola, Pterocarpus marsupium* also known as *Indian Kino, Malaban kino* and *Pitasara nenga* etc. (Kavishankar *et al*., 2011)

Cussonia arborea (Hochst) is a tree that originated from Africa and has its center of distribution in South Africa and Madagascar (Tennant, 2010). The tree can grow up to 11m tall with bole of up to 0.75 diameter; bark deeply fissured and corky. Leaves are digitately compound; petiole up to 87cm long and 9 mm wide but usually much smaller, mortly glabrous or some what hairy in places. Leaflets: 5-9 sessile, chartaceous to coriaceous to oblanceolate, ovate and obviate up top 23cm long by 10.5cm wide. Flowering spikes up to about 26 together but mostly less than 12, up to 46 cm long sometimes galled.

The different local names of the plant are Mufenje by Yoruba, Hannun kuturuu (Lepers Hand), takandar giiwaa (elephant sugarcane) by Hausa, Ityovor by TIV people and Kijagaajaga by Bukoba rural district in Tanzania. No specific Igbo name has been associated with the plant.

1.2 Background of the study

The search and development of a novel chemical molecule from medicinal plants that can be used for treatment of diabetes with little or no side effects is the driving force for this study. Most of the drugs in use are known to cause serious adverse side effects with various disadvantages.

The sulfonylureas for instance have increased risk of hypoglycaemia. They have high risk of death compared to melformin. The biguanides such as metformin are associated with increased risk of gastrointestinal problems. They are contraindicated for people with moderate or severe kidney disease or heart failure because of risk of lactic acidosis due to alcoholism. Metformin has increased risk of causing Vitamin B12 deficiency (Agabegi and Agabegi, 2008). It is also less convenient in dosing due to its metallic taste. The Alpha glucosidase inhibitors such as acarbose are less effective than most other diabetes pills in decreasing glycated hemoglobin. They also have increased risk of gastrointestinal problems than other diabetes pills except metformin. They are expensive and inconvenient in dosing with increased risk of edema and anaemias with increases in low density lipoprotein while the thiazolidinediones such as Pioglitazone have slow onset of action and requires monitoring for hepatotoxicity. They are expensive and have increased risk of limb fractures. They have also been associated with high risk of bladder cancer (Cambon-Thomsen *et al.,* 2007; Bennet *et al.,* 2011).

1.3 Statement of the problem

1. In the last two decades, research into antidiabetic medicinal plants has not been rewarded with marketable novel drugs (Dewanjee *et al.,* 2008).
2. The available synthetic hypoglycaemic agents used in clinical practice have serious adverse effects; therefore the search for more effective and safer antidiabetic agents has become an area of active research.
3. The synthetic drugs used presently are given for a long duration and have complicated mode of intake. There is no single agent that yields optimal glucose lowering effects in all treated patients.
4. Most ethnomedical practices lack scientific procedures and their effects sometimes are over exaggerated or based on trial and error.

1.4 Objectives of the study

The main objectives of this study include;

1. To establish the pharmacological basis for the use of the root bark of *C. arborea* in the treatment of symptoms of diabetes mellitus with a view to determining the efficacy and possibly biomedical mechanism(s) of action of the plant.
2. To isolate, characterize and carry out structural elucidation of the active compound(s) responsible for the anti-diabetic activity of the plant.
3. To evaluate the antioxidant potential of the plant.
4. To assess the toxicity of the extract.
5. To determine the biochemical effects associated with the plant in the treatment of *Diabetes mellitus*.

CHAPTER TWO
LITERATURE REVIEW

2.1 History

The term *Diabetes mellitus* is a group of metabolic diseases in which a person has high blood sugar either because the body does not produce enough insulin or because cells do not respond to the normally produced insulin (Shoback, 2011). Type 1 and type 2 diabetes were identified as separate conditions for the first time by the Indian physicians Sushruta and Charaka in 400-500 CE. Type 1 was associated with youth and type 2 with obesity (Leonid, 2009). The term mellitus or from honey was added by Thomas willis in the late 1600s to separate the condition from *Diabetes insipidus* which is also associated with frequent urination.

The first complete clinical description of diabetes was given by the ancient Greek physician Aretacus of Cappadocia (1st century CE), who also noted the excessive amount of urine which passed through the kidneys (Dallas, 2011). Although diabetes has been recognized since antiquity, and treatments of various efficacy have been known in various regions since the middle ages, and in legend for much longer, pathogenesis of diabetes has only been understood experimentally since about 1900 (Patlak, 2002). An effective treatment was only developed after the Canadians Frederick Banting and Charles Best first used insulin in 1921 and 1922 (Leonid, 2009).

The role of the pancreas in diabetes is generally ascribed to Joseph Von Mering and Oskar mikowski, who in 1889 found that dogs whose pancreases were removed, developed all the signs and symptoms of diabetes and died shortly afterwards (Von Mehring and Minkowski, 1890). In 1910, Sir Edward Albert Sharpey-Schafer suggested that people with diabetes were deficient in a single chemical that was normally produced by the pancreas. He proposed calling this substance insulin, from the Latin insulin meaning Island, in reference to the insulin-

producing Islets of langerhans in the pancreas. The islet of langerhans was discovered in 1869 by an anatomist named Paul Langerhans. He identified the keys cell in the pancreas which produces the main substance that controls glucose levels in the body (Bryan, 2004). Other landmark discoveries include development of the long acting insulin NPH in the 1940ôs Novo-Nordisk (Leonid, 2009), identification of the first sulfonylurea in 1942, reintroduction of the use of biguanides for type 2 diabetes in the late 1950s. Further more amino acid sequence of insulin was determined by Sir Frederic Sanger for which he received a Nobel prize. Insulin was the first protein that the amino acid structure was determined. There was also discovery of the three dimensional structure of insulin. The radioimmunoassay for insulin was discovered by Rosalyn Yalow and Solomon Berson (Yallow and Benson, 1960**)**. Thiazolidinediones were identified as effective insulin sensitizer during the 1990s (Polonsky, 2012).

2.2 Prevalence and incidence of DM

Middle aged to older dogs and cats are mainly affected by diabetes. In dogs, females are affected twice as often as males and the incidence appears to be increased in certain small breeds such as chow chow, Alaskan malamute, poodle etc. (Kahn, 2005). *Diabetes mellitus* affects 1:400 (0.25%) cats, though recent veterinary studies (McCann *et. al.,* 2007) noted that it is becoming more common lately in cats. In 2000, according to the WHO, at least 320 million people world wide suffered from diabetes (Wild *et. al.,* 2004). The prevalence of diabetes mellitus increases with age, and the numbers of older persons with diabetes are expected to grow as the elderly population increases in number. (Harris *et. al.,* **1998**).

2.3 Classification of Diabetes mellitus

The first widely accepted classification of diabetes mellitus was published by WHO in 1980 (WHO, 1980) and in modified form in 1985 (WHO 1985). The 1980 Expert committee proposed two major classes of *Diabetes mellitus* and named them insulin-dependent *Diabetes*

mellitus or type 1 and Non-insulin-dependent *Diabetes mellitus* or type 2. Gestational *Diabetes mellitus* (GDM) was regarded as the third. The recent classification as suggested by Kuzuya and Matsuda (1997) incude both the clinical stages and etiological types of *Diabetes mellitus*. The etiological classification reflects the fact that the defect or process which may lead to diabetes may be identifiable at any stage in the development of diabetes-even at the stage of nomoglycaemias. Therefore, the presence of islet cell antibodies in a normoglycaemic individual makes it likely that the person has the type 1 auto-immune process. The etiological types designate defects, disorders or processes which often result in *Diabetes mellitus*.

1. Type 1-Beta-cell destruction usually leading to absolute insulin deficiency.

a. Auto immune

b. Idiopathic

2. Type 2 (which may range from prominently insulin resistance with relative insulin deficiency to a predominantly secreatory defect with or without insulin resistance).

3. Gestational diabetes (which occur during pregnancy and may resolve after delivery or result to type 2).

4. Other specific types

a. Genetic defects of beta-cell function

i. Chromosome 20, HNF4$\propto$ (MODY 1)

ii. Chromosome 7, glucokinase (MODY2)

iii. Chromosome 12, HNFI$\propto$ (MODY 3)

iv. Chromosome 13, IPF-1 (MODY 4)

v. Mitochondrial DNA 3243 mutation

vi. Others

b. Genetic defects in insulin action

i. Type A insulin resistance

ii. Leprechaunism

iii. Rabson-Mendenhall syndrome

iv. Lipoatrophic diabetes

v. Others.

c. Disease of the exocrine pancreas

i. Fibrocalculous pancreatopathy

ii. Pancreatitis

iii. Trauma/pancreatectomy

iv. Neoplasia

v. Cystic fibrosis

vi. Haemochromatosis

vii. Others.

d. Endocrinopathies

i. Cushingôs syndrome

ii. Acromegaly

iii. Phaeochromocytoma

iv. Glucagonoma

v. Hyperthyroidism

vi. Somatostatinoma

vii. Others.

e. Drug or chemical induced

i. Nicotinic acid

ii. Glucocorticoids

iii. Thyroid homones

iv. Alpha-adrenergic agonists

v. Beta-adrenergeic agonists

vi. Thiazides

vii. Dilantin

viii. Pentamidine

ix. Vacor

x. Interferon-alpha theraphy

xi. Others.

f. Infections

i. Congenital rubella.

ii. Cytomegalovirus

iii. Others.

e. Uncommon forms of immune-mediated diabetes

i. Insulin autoimmune syndrome (antibodies to insulin).

ii. Anti-insulin receptor antibodies

iii. Staff man syndrome

iv. Others

g. Other genetic syndromes sometimes associated with diabetes

i. Downôs syndrome

ii. Friedreichôs ataxis

iii. Huntingtonôs chores

iv. Klinefelterôs syndrome

v. Lawrence-moon-Biedel syndrome

vi. Myofonic dystrophy

vii. Porphyrines

viii. Prader-Willi syndrome

ix. Turnerôs syndrome

x. Wolframôs syndrome

xi. Others

5. Type 3 diabetes mellitus (Alzheimerôs diseases)

It is also noteworthy that some researchers are currently considering Alzheimerôs disease as Type 3 diabetes mellitus.

2.3.1 Type 1 *Diabetes mellitus* (T_1DM)

Type 1 *Diabetes mellitus* results from the bodyôs failure to produce insulin and presently requires the patient to inject insulin for survival, thus insulin dependent *Diabetes mellitus* (IDDM). Type 1 *Diabetes mellitus* is characterized by loss of the insulin-producing beta cells of the islets of langerhans in the pancreas leading to insulin deficiency. The loss of beta cells could be immune-mediated or idiopathic. The majority of type 1 diabetes is of auto-immune-mediated nature in which beta cell loss is a T- cell-mediated autoimmune attack (Rother, 2007). There is no known preventive measure against type 1 diabetes which causes approximately 10% of *Diabetes mellitus* cases in North America and Europe. Most affected people are otherwise healthy and of a healthy weight when onset occurs. Sensitivity and responsiveness to insulin are usually normal, especially in the early stages. Type 1 diabetes can affect children or adults but was traditionally termed juvenile diabetes because a majority of these diabetes cases were in children (Humphray *et al.,* 1998).

2.3.1.1 Autoimmune type 1 *Diabetes mellitus*

It results from auto-immune mediated destruction of the beta cells of the pancreas. The rate of destruction varies being rapid in some individuals and slow in other (Zimmet *et al.,* 1994). The rapidly progressive form is commonly observed in children but may also occur in adults (Humphray *et al.,* 1998). The slowly progressive form generally occurs in adults and is sometimes referred to as latent autoimmune diabetes in adults (LADA). Individuals with this form of type 1 diabetes often become dependent on insulin for survival eventually and are at risk for ketoacidosis (Willis *et al.,* 1996). At this stage of the disease, there is little or no insulin secretion as manifested by low or undetectable levels of plasma C- peptide (Hother-Nielsen *et al.*, 1988). The peak incidence of this form of type 1 diabetes occurs in childhood and

adolescence but the onset may occur at any age, ranging from childhood to the ninth decade of life (Molbak *et al.,* 1994). There is genetic predisposition to autoimmune destruction of beta cells, and it is also related to environmental factors that are still poorly defined. Although patients are usually not obese when they present with this type of diabetes, the presence of obesity is not incompatible with the diagnosis. These patients may also have other auto-immune disorders such as Gravesô disease, Hashimotoôs thyroiditis and Addisonôs disease (Betterle *et al.,* 1983).

2.3.1.2 Idiopatic type 1 *Diabetes mellitus*

This is a form of type 1 diabetes mellitus which has no known aetiology. Some of these patients have permanent insulinopenia and are susceptible to keto-acidosis but have no evidence of autoimmunity (Mclarty *et al.,* 1990). This form of diabetes is more common among individuals of African and Asian origin. In another form found in Africans, an absolute requirement for insulin replacement therapy in affected patients may come and go and patients periodically develop ketoacidosis (Ahren and Corrigan, 1984).

2.3.1.3 Pathogenesis of type1 DM

Its transmission is believed to be an autosomal dominant, recessive or mixed chromosome, although no mechanism is proven. Researchers believe that onset of type 1 seems to be linked with an environmental insult, an allergen such as cowôs milk or a virus that initiate this process in genetically susceptible individual. There are certain viruses that seem to destroy the pancreatic beta cells directly rather than through an autoimmune reaction (Mijac *et al.,* 1997). Researchers have also found a significant correlation between antibodies to cowôs milk protein especially to bovine serum albulmin in the onset of IDDM (Karjalainen *et al.,* 1992). Cowôs milk seems to be strongly linked to the onset of type 1.

2.3.2 Type 2 *Diabletes mellitus*

Type 2 *Diabetes mellitus* is characterized by insulin resistance, which may be combined with relatively reduced insulin secretion (Shoback, 2011**)** due to defection in insulin receptor. *Diabetes mellitus* of this type previously included non-insulin dependent diabetes or adult onset diabetes. It is a term used for individuals who have relative (rather than absolute) insulin deficiency. Individuals who have this type of diabetes are frequently resistant to the action of insulin (Lillioja *et al.,* 1993). The majority of patients with this form of diabetes are obese, and obesity itself causes or aggravates insulin resistance (Bogardus *et al.,* 1985). Many of those who are not obese by traditional weight criteria may have an increased percentage of body fat distributed predominantly in the abdominal region (Kissebah *et al.,* 1982). Ketoacidosis is infrequent in this type of diabetes, when seen it usually arises in association with the stress of another illness such as infection (Banerji *et al.,* 1994**)** whereas patients with this form of diabetes may have insulin levels that appear normal or elevated, the high blood glucose levels in these diabetes patients would be expected to result in even higher insulin values had their beta-cell function been normal (Polonsky *et al.,* 1996). Thus, insulin secretion is defective and insufficient to compensate for the insulin resistance. On the other hand some individuals have essentially normal insulin action, but markedly impaired insulin secretion. Insulin sensitivity may be increased by weight reduction, increased physical activity, and or pharmacological treatment of hyperglycemia but is not restored to normal (Wing *et al.,* 1994).

2.3.2.1 Pathogenesis of type 2 Dm

The main cause of insulin resistance is a lack of communication between the insulin, a chemical messenger and the receivers of the signal, a significant amount of which are called GLUT-4 transporters. Glut-4 transporters are proteins within the cell that rise to the cellôs

membrane, take hold of the glucose and bring it inside the cell. Insulin resistance implies that cells do not receive the insulin signaling message clearly and do not respond appropriately. Consequently, blood sugar levels remain high, causing pancreatic beta cells to pump out more insulin to ñknockò louder on the cell walls. At the onset of the disease process, the glucose is let in, even with insulin resistance. This is referred to as compensated insulin resistance as the pancreas has put out more insulin and glucose level stabilizes for a while. Eventually, over time, the beta cells of the pancreas are either inflamed or worn out. About 30 percent of the people with type 2 diabetes do inject insulin daily because their insulin-producing cells have become destroyed (Cousen, 2008). These type 2 (NIDDM) diabetics become insulin-dependent diabetes (IDDM).

2.3.3 Gestational *Diabetes mellitus* (GDM)

Gestational *Diabetes mellitus* (GDM) is third major category of diabetes. Gestational diabetes is carbohydrate intolerance resulting in hyperglycemias of variable severity with onset or first recognition during pregnancy. Gestational *Diabetes mellitus* resembles type 2 diabetes in several respects involving a combination of relatively inadequate insulin secretion and responsiveness. It occurs in about 2-5% of all pregnancies and may improve or disappear after delivery. Gestational diabetes is fully treatable, but requires careful medical supervision throughout the pregnancy. About 20-50% of affected women develop type 2 diabetes later in life. In fact, the rate of diabetes in expectant mothers has more than doubled in the past six years (Lawrence *et al.,* 2008). This is particularly problematic as diabetes raises the risk of complications during pregnancy, as well as increasing the potential for the children of diabetic mothers to become diabetic in the future.

2.3.3.1 Pathogenesis of GDM

This is as a result of the metabolic changes that occur during a normal pregnancy to conserve sugar for the foetus. The motherôs placenta produces hormones that naturally increase insulin resistance, thus redirecting some of the sugar to her fetus that before pregnancy would have gone to her cells. Early in pregnancy maternal estrogen and progesterone increase and help in pancreatic beta cell type hyperplasias and increased insulin production (Kuhl and Holst, 1976). This rise in insulin enhances peripheral glucose utilization and glycogen storage and lower glucose levels, but this shifts as the pregnancy progresses. Cortisol which has the highest diabetic creating potency peaks at 26 weeks. Progesterone with anti-insulin qualities peaks at 32 weeks. These two periods 26 and 32 weeks, encompasses an important time during which the pancreas releases 1.5 to 2.5 times more insulin to respond to the resistance (Freinkel, 1980).

2.3.3.2 Table 1: The diabetogenic potency of hormones in pregnancy

Hormone	1 peak elevation	Diabetigenic potency
Prolaction	10	Weak
Estradiol	26	Very weak
HCG	16	Moderate
Cortisol	26	Very strong
Progesterone	32	Strong

(Cousens, 2008)

2.3.4 Other specific types

2.3.4.1 Genetic defects of beta-cell function

These defects are usually autosomal in inheritance. Maturity onset diabetes of the young (MODY) is one form that is usually characterized by impaired insulin secretion with minimal or no defect in insulin action (Clement *et al.,* 1996).

The most common form is associated with mutations on chromosome 12 in a hepatic nuclear transcription factor referred to as HNF_1 (Yamagata, *et al.,* 1996). A second form is associated with mutations of the glucokinase gene on chromosome 71 (Froguel *et al.,* 1992). Glucokinase converts glucose to glucose-6-phosphate, the metabolism of which in turn stimulates insulin secretion by the beta cell. This glucokinase serves as the ñglucose sensorô for the beta cell. Because of the defect in glucokinase gene, increased levels of glucose are necessary to elicit normal level of insulin secretion. A third form is associated with a mutation in the $HNF_{4,}$ (a transcription factor which is involved in the regulation of the expression of HNF_1 gene) on chromosome 20_q (Yamagata *et al.,* 1996). Fourth variant has recently been ascribed to mutation in another transcription factor gene, IPF-1 which in its homozygous form leads to total pancreatic agenesis (Stoffers *et al*., 1997). Specific genetic defects in other individuals who have a similar clinical presentation are currently being defined. Point mutations in mitochrondria DNA have been found to be associated with diabetes mellitus and deafness (Walker and Turnbull, 1997). The most common mutation occurs at position 3243 in the tRNA leucine gene leading to an A to G substitution. An identical lesion occurs in the MELA syndrome (Mitochondria myopathy, encephalopathy, lactic acidosis and stroke-like syndrome), however, diabetes is not part of this syndrome, suggesting that there are other reasons different from phenotypic expression of the genetic lesion (Johns, 1995).

Genetic abnormalities that result in the inability to convert pro insulin to insulin have been identified in a few families. Such traits are usually inherited in an autosomal pattern (Robbins *et al.,* 1984) and the resultant carbohydrate intolerance is mild. Similarly mutant insulin molecules with impaired receptor binding have been identified in a few families. These are also associated with autosomal inheritance and either normal or only mildly impaired carbohydrate metabolism (Haneda *et al.*, 1984).

2.3.4.2 Genetic defects in insulin action

There are some unusual causes of diabetes which result from genetically determined abnormalities of insulin action. The metabolic abnormalities associated with mutations of the insulin receptor may range from hyperinsulinaemia and modest hyperglycaemia to symptomatic diabetes (Taylor, 1992). Some individuals with these mutations have Acanthosis nigricans. Women may have virilization and have enlarged cystic ovaries. In the past, this syndrome was termed type A insulin resistance (Kahn *et al.,* 1976) Leprechaunism and Rabsom-mendenhall syndrome are two pediatric syndromes that have mutations in the insulin receptor gene with subsequent alterations in insulin receptor function and extreme insulin resistance (Taylor, 1992).

2.3.4.3 Disease of the exocrine pancreas

Any process that generally injures the pancreas can cause diabetes. Acquired processes include pancreatitis, trauma, infection, pancreatic carcinoma and pancreatectomy (Larsens *et al.,* 1987). With the exception of cancer, damage to the pancreas must be extensive for diabetes to occur. However, adenocarcinomas that involve only a small portion of the pancreas have been associated with diabetes. This implies a mechanism other than simple reduction in beta cell mass

(Permert *et al.,* 1994). If extensive enough, cystic fibrosis and haemochromatosis will also damage beta cells and impair insulin secretion (Moran *et al*., 1994**).**

2.3.4.4 Endocrinopathies

Some hormones (e.g growth hormone, cortisol, glucagon, epinephrine) antagonize insulin action. Diseases such as Acromegaly, Cushingôs syndrome, Glucagonoma and Phaeochromoly associated with excess secretion of these hormones can cause diabetes (McFarlane, 1997). These forms of hyperglycecmia typically resolve when the hormone excess is removed.

Somatostatinoma and aldosteronoma-induced hypokalemia can cause diabetes at least in part by inhibiting insulin secretion (Krejs *et al.,* **1**979).

2.3.4.5 Drug or chemical-induced DM

The drugs that can impair insulin secretion may not by themselves cause diabetes but they may precipitate diabetes in individuals with insulin resistance (Pandit *et al.,* 1993). In such cases, the classification is ambiguous as the primacy of beta cell dysfunction or insulin resistance is unknown. Certain toxins such as Vacor (a rat poision) and pentamidine can permanently destroy pancreatic beta cells (Esposti *et al.,* 1996). There are also many drugs and hormones which can impair insulin action. Examples include nicotinic acid and glucocorticoids (Yajnik *et al.,* 1992).

2.3.4.6 Infection

Some viruses have been associated with beta cell destruction. Diabetes occurs in some patients with congenital rubella (Forrest *et al.,* 1971). In addition, coxasackie B, Cytomegalovirus and other viruses (eg adeno virus and mumps) have been implicated in inducing the disease (Pak *et al.,* 1988)**.**

Uncommon but specific forms of immune-mediated *Diabetes mellitus*

Diabetes may be associated with several immunological diseases with aetiology different from that which leads to the type 1 diabetes process. Postprandial hyperglycaemia of a severity sufficient to fulfill the criteria for diabetes has been reported in rare individuals who spontenously develop insulin auto antibodies (Bodansky *et al.*, 1986). However these individuals generally present with symptoms of hypoglycaemia rather than hyperglycaemia. The ñstiff manò syndrome is an autoimmune disorder of the central nervous system characterized by stiffness of the axial muscles with painful spasms (Solimena and Decamilli, 1991). Affected people usually have high titres of the GAD auto antibodies and approximately one half will develop diabetes. Patients receiving interferon alpha have been reported to develop diabetes associated with islet cell auto antibodies and in certain instances, severe insulin deficiency (Fabris *et al.*, 1992).

Anti-insulin receptor antibodies can precipitate diabetes by binding to the insulin receptor, thereby reducing the binding of insulin to target tissues (Flier, 1992). However, these antibodies also can act as an insulin agonist after binding to the receptor and can thereby cause hypoglycaemia (Kahn *et al.,* 1977). Anti-insulin receptor antibodies are occasionally found in patients with systemic hispus erythematous and other autoimmune diseases (Tsokos *et al.,* 1985).

2.3.4.7 Other genetic syndromes sometimes associated with diabetes

Many genetic syndromes are accompanied by an increased incidence of diabetes mellitus. These include the chromosomal abnormalities of Downôs syndrome, Klinefelters syndrome and Turnerôs syndrome. Wolfranôs syndrome is an autosomal recessive disorder characterized by insulin-deficient diabetes and the absence of beta cells at autopsy (Barret *et al.,* 1995). Additional manifestations include diabetes insipidus, hypogonadism, optic atrophy and neural deafness.

2.3.5 Type-3 *Diabetes mellitus* (Alzheimer's disease)

Alzheimerôs disease is a neurological disorder characterized by profound memory loss and progressive cognitive and behavioural decline due to selective loss or dysfunction of neurons in specific brain regions/neural circuits, including the neocortex, hippocampus, and basal forebrain (Mattson, 2004). Alzheimerôs disease is currently being associated with diabetes, obesity and heart disease. Some researches refer to the disease as type 3 DM (Rivera *et al.,* 2005). A variety of studies have shown that individuals with type-2 diabetes have greater chances of developing Alzheimerôs. The current theories implicate poor brain circulation caused by diabetes as a primary factor as well as insulin resistance in the areas of the brain responsible for memory and recognition, such as the limbic system, hippocampal, cortical and precortical areas. New research linking diabetes and Alzheimerôs suggest that the high blood sugar of diabetes can lead to the formation of advanced glycation end products (AGEs) (Takeuchi *et al.*, 2004).

2.4 Clinical signs of DM

The classic signs and symptoms of *Diabetes mellitus* are the three polysô---------polyuria (excessive urination), polydipsia (excessive thirst) and polyphagia (excessive hunger).

The kidneys cannot absorb the ever-increasing glucose, so the excess is excreted in the urine. The brain is prompted by this loss of fluid signals, thirst and hunger. If this process continues, stored fats are metabolized which leads to lower pH levels and acidosis. The drop in PH levels and loss of ketones in urine signals the onset of ketoacidosis. Intracellular potassium ions are exchanged for hydrogen along with sodium, magnesium and phosphorus. Blood volume drops increasing haematocrit, haemoglobin and white blood cell counts. Respiratory

compensation results in laboured, deep respiration (Kussmaul respiration) in an attempt to lower the partial pressure of carbon dioxide (PCo_2) values. This process is acute but may extend over several days. Keto acidosis is a likely presenting symptom in an initial type 1 diagnosis (ADA, 1997).

In addition to the classic signs of diabetes listed above, type 1 diabetes presents the following signs and symptoms.

- Weakness and fatigue
- Drowsiness.
- Irritability
- Blurred vision or any change in sight
- Nausea and vomiting
- Sudden unexplained weight loss (Cook and Plotnic, 2008)

In type 2 *Diabetes mellitus*, the symptoms are usually insidious (develops slowly) and also include the following:

- Polyuria, polydipsia, polyphagia, weakness and fatigue, drowsiness, irritability, blurred vision, tingling or numbness in legs, feet or finger, slow healing of cuts (especially on feet), frequent skin or vaginal infections or itchy skin (Cook and Plotnick, 2008).

Signs and symptoms of diabetic ketoacidosis found in type-1 include: hyperglycaemia, Glycosuria, weight loss, nausea and vomiting, deep labored respiration, fatigue and abdominal pain (Bruno *et al*., 1990).

In dogs (with usually type 1 DM), the common signs include polydipsia, polyuria, polyphagia with weight loss, bilateral cataracts and weakness. The renal threshold for glucose is 180 mg/dl in dogs and 240 mg/dl in cats. Cataract formation in dogs is related to the unique

sorbitol pathway in which glucose is metabolized in the lens which leads to edema of lens and disruption of normal light transmission (Aiello *et al.,* 1998).

In cats, (with usually type 2 DM), the first obvious symptoms are sudden weight loss or gain accompanied by excessive drinking and urination; for example, cats can appear to develop an obsession with water and lurk around faulets or water bowls. Appetite is either ravenous or absent. In cats, the back legs may become stilted wobbly because of peripheral neuropathy. Lethargy and limpness are acute symptoms indicating likely ketoacidosis and or dehydration (Rand and Marshal, 2005).

Generally speaking, diabetic animals have decreased resistance to bacterial and fungal recurrent infections such as cystitis, prostitis bronchopneumonia and dermatitis (Rand and Marshal, 2005).

2.5 Complications of *Diabetes mellitus*

2.5.1 Acute complication

Acute complications of diabetes mellitus include diabetic ketoacidosis (DKA), hyperglycemic hyperosmolar state, respiratory infections, hypoglycemia or hyperglycemia.

Diabetic ketoacidosis (DKA) is an acute and dangerous complication that is always a medical emergency. Low insulin levels cause the liver to turn to fat for fuel leading to production of ketone bodies (ketosis). Elevated levels of ketone bodies in the blood decrease the blood pH leading to DKA. Common signs of DKA include abdominal pains, lethargy, coma, hypotension, shock and death. Urine analysis will reveal significant levels of ketone bodies (which appear in the urine after exceeding its renal threshold) (Aiello *et al.*, 1998). Therapy include correcting dehydration, by administration of IV fluids such as 0.09% NaCl or lactated Ringers solution; reducing hyperglycemia and ketosis by administration of crystalline Zinc (regular) insulin,

maintaining serum electrolyte levels especially potassium; insulin regimen such as regular insulin at 0.2 mg/kg IM in the initial dose, followed by hourly administration of 0.1mg/kg (Kahn, 2005).

DKA may be the presenting symptom in individuals previously undiagnosed with type-1 DM and it is likely seen in type 1 diabetics if they have not received enough insulin during times of illness. Type-2 diabetes may experience DKA if they are very ill and not able to eat sufficient calories. Other factors include overeating and physical inactivity. DKA usually occurs when blood glucose levels are over 240 mg/dl. Mortality rates range from less than 5% to 14% (Cherry-pepper *et al*., 1992).

Hyperglycemic hyperosmolar syndrome (HHS) accounts for 5-15% of hospital admission for diabetes coma (Patterson, 2005). Mortality rates are reported as high as 50% (Cherry-pepper, *et al.*, 1992). This disorder resembles DKA (dehydration, altered mental status) although blood glucose levels are much higher (up to 2000 mg/dl), Kussmaul respiration is rare and there is absence of ketosis. There is a reduction in the rate of glomerular filteration and glucose excretion (Patterson, 2005). Hyperglycemic hyperosmolar syndrome occurs mostly in diagnosed and undiagnosed type-2 diabetics over the age of 60. Conditions or events that precipitate HHS include: History of type 2 diabetes, chronic illness, acute illness (eg stroke, myocardial infarction), mild renal insufficiency, lack of normal thirst drive or access to water, drugs (diuretic, glucocorticoids) surgery, dialysis, (Cherry-pepper *et al*., 1992). Individuals may exhibit central nervous system distress (e.g hallucinations, focal or grand mal seizures). Treatment is similar to that of DKA and consists of intravenous administration of fluids, electrolytes and insulin. The result of the treatment may make the patient sensitive to further insulin. Glucose control can be attained through a combination of diet, exercise and oral hypoglycemic agents or

insulin. Patient education should include an understanding of the warning signs of onset of HHS and glucose monitoring techniques (Rees, 1994).

Hyperglycemia is another diabetic emergency. If left unchecked, chronic hyperglycemia can result in diabetic ketoacidosis or hyperglycemic hyperosmolar nonketotic coma. These conditions develop over days but will develop more quickly if the individual is concurrently suffering an illness or infection (Cherry-Pepper, *et al.,* 1992).

The most common acute diabetic emergency in the dental office is hypoglycemia (FDA, 2010). Most diabetics begin to have symptoms when the blood glucose level falls below 70 mg/dl. Persons with long standing type 1 diabetes may have decreased ability to sense impending hypoglycemia (Oliver and Tellervo, 1993). Symptoms of hypoglycemia may include: headache, hunger, moist skin, pallor, weakness, dizziness, anxiety and confusion. If left untreated, these symptoms may progress to severe hypoglycemia, loss of consciousness leading to seizures and possible death (Cherry-Pepper- *et al.,* 1992). In the condition of hypoglycemia, individuals should consume 10-15 g of rapidly absorbable carbohydrate such as 3 glucose tablets, fruit juice, 5-7 hard candies, milk, 1 tablespoon of sugar or sugar cube, regular soft drink (not diet), cake icing.

A respiratory infection is another acute complication. The immune response is impaired in individuals with *Diabetes mellitus*. Cellular studies have shown that hyperglycemia both reduces the function of immune cells and increases inflammation. The vascular effects of diabetes also tend to alter lung function, which leads to an increase in susceptibility for respiratory infections such as pneumonia and influenza among individuals with diabetes. Several studies also show diabetes associated with a worse disease course and slower recovery from respiratory infections (Ahmed *et al.,* 2008).

2.5.2 Chronic complication

The underlying cause of chronic complications in both type-1 and type-2 diabetes are consequent upon two main metabolic problems: the glycosylated proteins/lipids and the intracellular accumulation of sorbitol.

For example glycosylated low-density lipoproteins (LDL) do not bind to LDL receptors and are therefore not capable of blocking off the endogenous cholesterol synthesis. The result is increased tendency of cholesterol accumulation. Sorbitol accumulation inside the cells is another major serious metabolic problem. In a normal physioiology, once the sorbitol is produced, it is metabolized in polyol pathway by polyol dehydrogenase to fructose. This conversion to fructose allows it to be excreted from the cell. In the diabetics with excessive blood sugars, the sorbitol accumulates and plays a major role in the development of secondary complications.

Diabetic nephropathy

Diabetic nephropathy is a chronic complication of both type-1 DM and type-2 DM. There are five stages in the development of diabetic nephropathy.

Diabetic nephropathy is a common cause of high rates of dialysis and death. Once people begin kidney dialysis, the diabetic process affects the kidneys in a few ways: glomerulosclerosis, and arteriosclerosis of the entering and leaving renal arteries; arteriosclerosis of the renal artery and its internal branches; and deposits of glycogen, fat and glycopolysaccharides around the tubules. Early on, nephropathy has no symptoms, but as it advances we see edema (swelling, particularly around the eye), nausea, fatigue, headache, and generalized itching (Cousens, 2013).

Diabetic cardiomyopathy

Diabetic cardiomyopathy refers to a disease process which affects the myocardium in diabetic patients causing a wide range of structural abnormalities eventually leading to left

ventricular hypertrophy and diastolic and systolic dysfunction or a combination of these. The concept of diabetic cardiomyopathy is based upon the idea that diabetes is that factor which leads to changes of the cellular levels leading to structural abnormalities (Factor *et al*., 1981).

Molecular basis for diabetic cardiomyopathy can be explained by the interaction among hyperglycemic, hyperlipidemic and increased ROS (reactive oxygen species) which induce alterations in down-stream transcription factors that result in changes in gene expression, myocardial substrate utilization, myocyte growth, endothelial function and myocardial compliance (Zhou *et al.*, 2001).

Diabetic encephalopathy

The brain makes use of glucose as the main fuel to generate energy, mainly by oxidative metabolism. However, a prolonged increase in blood glucose levels, even in the absence of *Diabetes mellitus* symptoms will eventually lead to brain damage (Rosseti *et al.*, 1990). Thus hyperglycaemia-induced neurotoxicity has been implicated as one of the main causes of diabetic encephalopathy (McCall, 2004). The advanced glycation end products (AGEs) AGE receptor (RAGE) axis and the polyol pathways may represent molecular mechanisms of glucose neurotoxicity (Browlee, 2000).

Diabetic neuropathy

Diabetic neuropathies are family of nerve disorders caused by diabetes. People with diabetes can over time, develop nerve damage throughout the body such as pain, tingling or numbness in hands, arms, feet and legs, wasting of the muscles, indigestion, nausea or vomiting, diarrhoea, constipation, dizziness due to a drop in blood pressure after standing or sitting up, problems with urination, erectile dysfunction in men or vaginal dryness in woman, weakness etc.

Diabetic neuropathies could be peripherial neuropathy, autonomic neuropathy, proximal neuropathy or focal neuropathy.

Diabetic neuropathy is associated with decreased sensory and nerve conduction velocities. Diabetic neuropathy also seems to be associated with sorbitol accumulation. Sorbitol accumulation leads to myoinosotol loss. Inositol helps create healthy nerve conduction. Typically, this peripheral neuropathy is associated with parenthesis, hyperesthesias and pain. On the neurological exam, almost every diabetic has some level of poor vibratoy sense, altered pain and temperature sense and poor deep tendon reflexes (Wyngaarden *et al*., 1992**)**

Diabetic foot complications are the most common cause of non trauma-based lower extremity amputations in the industrialized world. Neuropathy, a major etiologic component of most diabetic ulcerations, is present in more than 82 percent of diabetic patients with foot wounds (Pecoraro *et al*.,1990).

Diabetic retinopathy

Diabetic retinopathy is the leading cause of blindness in diabetics. In diabetic retinopathy, the retinal vessels in the eye weaken and develop micro aneurisms that leak blood plasma out of the capillaries. This results in scarring in the eye, which leads to gradual blindness. It is related to glycosylated hemoglobin and seems to increase when the glycosylated hemoglobin goes above 6%.

In diabetic retinopathy, the pericytes of the retinal capillaries are injured, which is associated with defective capillary function (Saphieha *et al.,* 2010). Such capillary deficiency is associated with defects in proper oxygen delivery and nutrient supply resulting in vascular endothelial growth factor (VEGF) over production in the retina (Kermorvant-Duchemin *et. al.*, 2010). This VEGF over production is also associated with abnormal angiogenesis and enhanced

retinal capillary permeability, resulting in retinal dysfunction associated with the loss of visual acuity in these patients (Saphieha *et al.*, 2010).

Dental disease

Periodontal (gum) disease is more common among people with diabetes. Among young adults, those with diabetes have about twice the risk of those without diabetes. Almost one-third of people with diabetes have severe periodontal disease with loss of attachment of gums to the teeth measuring 5 millimeters or more. Improving your dental health can also help with glycemic control (Ross-Flanigan, 1999).

Diabetic cataract

During hyperglycemia, extracellular glucose diffuse into the lens, this can lead to the post-translational modification. Cataract progresses from the production and accumulation of excessive sorbitol in the lens fibre and consequent osmotic stress. Sorbitol which is synthesized from aldose reductase utilizing the NADPH does not cross the cell membranes; it can accumulate in the cells and can cause cell damage due to disturbing osmotic homeostasis (Gupta *et al*., 2009). Reduction in concentration of glutathione, antioxidant enzymes such as catalase, superoxide dismutase (SOD), glutathione reductase, glutathione peroxidase with increase in age were the main factor involving the generation of cataract (Graw, 2009).

Diabetic angiopathy

Vascular diseases such as damage of blood vessels (angiopathy) are consequent upon chronic elevation of blood glucose levels. The endothelial cells lining the blood vessels take in more glucose than normal, since they do not depend on insulin. This makes them to form more surface glycoprotein than normal and cause the basement membrane to grow thicker and weaker. Non-diabetic off-spring of type 2 diabetics has been found to have increased arterial stiffness and

neuropathy despite normal blood glucose levels (associated with diabetic renal disease) (Ban and Twigg, 2008).

The damage to small blood vessels (microangropathy) has been incriminated in the pathogenesis of diabetic neuropathy, nephropathy, encephalopathy, retinopathy and cardiomyopathies as discussed earlier.

2.6 Diagnosis of DM

Diabetes mellitus can be diagnosed using the following:

1. Clinical signs

2. Fasting blood sugar

3. Oral glucose tolerance test

4. Glycated haemoglobin HbA_{1c}

5. Insulin sensitivity test

6. Insulin assay

7. Urinary sugar

For individuals with symptoms of diabetes such as excessive thirst and urination or unexplained weight loss, only elevated fasting plasma glucose (Ó140 mg/dl) or random plasma glucose Ó200 mg/dl is required to confirm the diagnosis.

In 1997, the first expert committee on the diagnosis and classification of *Diabetes mellitus* revised the diagnostic criteria between Fasting Plasma Glucose (FPG) levels and presence of retinopathy as the key factor with which to identify threshold glucose levels. The committee examined data from three cross-sectional epidemiological studies that assessed retinopathy with fundus photography or direct ophthalmoscope and glycemia as FPG, 2-h plasma

glucose (PG), and glycosylated haemoglobin (HbA_{1c}). These studies demonstrated glycemic levels below which there was little prevalent retinopathy and above which the prevalence of retinopathy increased in an apparently linear fashion. The deciles of the three measures at which retinopathy began to increase were the same for each measure within each population. Moreover, the glycemic values above which retinopathy increased were similar among the populations. These analyses helped to inform a new diagnosis cut point Ó126 mg/dl (7.0 mmol/l) for FPG and confirmed the long-standing diagnostic 2-h plasma glucose (PG) value of Ó200mg/dl (11.1mmol/l) (IEC, 2009).

Glycosylated haemoglobin (HbA_{1c}) is a widely used marker of chronic glycemia, reflecting average blood glucose levels over a two to three month period of time. The test plays a critical role in the management of the patient with diabetes since it correlates well with both microvascular and to a lesser extent, macrovascular complication and it is widely used as standard biomarker for the adequacy of glycemic management (IEC, 2009). An international expert committee, after an extensive review of both established and emerging epidemiological evidence, recommended the use of the HbA_{1c} test to diagnose diabetes with a threshold of ≥ 6.5% and American diabetes Association affirms this. The diagnostic HbA_{1c} cut point of 6.5% is associated with an inflection point for retinopathy prevalence, as well as the diagnostic thresholds for FPG and 2-h plasma glucose (IEC, 2009).

2.6.1 Formation of glycosylated haemoglobin (HbA_{1c})

Glycosylated haemoglobin is the result of simple chemical reaction between haemoglobin and sugars after synthesis of hemoglobin is complete that is post-translational modifications (Bunn *et al.*, 1976). The reaction proceeds in 2 stages.

1. Glucose combines with alpha amino group of the valine residual N-terminus of beta (β) globin chains to form aldimine compound (Schiff base). This reaction is reversible and dissociation to native hemoglobin and glucose occurs readily.
2. Internal rearrangement of the aldimine intermediate by the Amadori reaction yields a stable ketoamine derivative.

Early workers confirmed that glycosylation begins during erythropoeiesis and continues slowly through out the life of hemoglobin in the circulation; concentrations reached in the red cell of diabetic subjects are consistent with their known life span of about 120 days (Bunn *et al.,* 1976).

2.6.2 Criteria for diagnosis of diabetes in non pregnant adult

Any one of the following as shown on the table below is considered diagnostic of diabetes.

Table 2: Diagnosing diabetes

Test	Result	Interpretation
HbA1c	6.5% or higher	Diabetes
	5.7-6.4%	Impaired glucose tolerance
	Lower than 5.7%	Normal
Random plasma	200 mg/dl or higher	Diabetes
	140-199mg/dl	Impaired glucose tolerance
	Lower than 140 mg/L	Normal
Fasting plasma	126 mg/dl or higher	Diabetes
Glucose	100-125 mg/dl	Impaired glucose tolerance
	Lower than 100mg/dl	Normal

(Amantel *et al*., 2013)

Table 3: Values for diagnosis of *Diabetes mellitus* and other categories of the hyperglycemic glucose concentrations (mMol/L (mg/dl))

Diabetes mellitus	Whole venous	Blood capillary	Plasma venous
Fasting or 2-hour post glucose load	Ó6.1 (Ó110) Ó10 (Ó180)	Ó6.1 (Ó110) Ó11.1 (Ó200)	Ó7.0 (Ó126) Ó11.1 (Ó200)
Impairs glucose tolerance: fasting (4 measured) and 2-hour post glucose load	>6.1 (>110) Ó6.7 (Ó120) and >100 (>180)	> 6.1 (> 110) Ó7.8 (Ó140) and >11.1 (<200)	>7.0 (>126) Ó7.8 (Ó140) and <11.1 (<200)
Impaired fasting glycaemia fasting and (if measured 2-hour doit glucose load	Ó5.6 (Ó110) and 6.1 (<110 < 6.7 (<120)	Ó5.6 (Ó100)and < 6.1 (<110) < 7.8 (<140)	Ó6.1 (Ó110) and <7.0 (126) <7.8 (<140)

(Amantel *et al*., 2013)

In 1997 and 2003, the expert committee on diagnosis and classification of *Diabetes mellitus* (Genuth *et al.,* 2003) recognized an intermediate group of individuals whose glucose levels do not meet criteria for diabetes, yet are higher than those considered normal. These people were defined as having impaired fasting glucose (IFG) FPG level of 100 mg/dl (5.6mmol/L) to 199mg/dl 11.0 mmol/L).

Individuals with IFG and or IGT have been referred to as having pre-diabetes, indicating the relatively high risk for the future development of diabetes. IFG and IGT can be observed as intermediate stages in some disease process. They are associated with obesity (especially abdominal or visceral obesity), dyslipidemia with high triglycerides and or low HDL-cholesterol and hypertension. Structure life style intervention, aimed at increasing physical activity and producing 5-7 % loss of body weight and certain pharmacological agents have been demonstrated to present or delay the development of diabetes in people with IGT, the potential impact of such interventions to reduce mortality or the incidence of cardiovascular disease has not been demonstrated to date.

2.6.3 The oral glucose tolerance test (OGTT)

In symptomatic individuals with random plasma glucose value >200 mg/dl, the OGTT is not required for a diagnosis of diabetes. However, in asymptomatic individual and to establish a diagnosis of IGT, the OGTT is necessary (WHO, 1980; WHO, 1985). The test should be performed in the morning on subjects who have had at least 3 days of unrestricted diet. The subject should have fasted overnight for 10-16 hours and remain seated and not smoke throughout the test. A fasting blood sample should be collected, after which the subjects should drink 75 g of glucose in a concentration no greater than 25 g per 100 ml. The OGTT is the

internationally recognized standard for diagnosing a symptomatic NIDDM (WHO, 1980**;** WHO 1985)**.**

Fasting plasma glucose (FPG)

In the U.S population, there is a broad distribution of FPG among adults with undiagnosed NIDDM and only approximately 26 percent of people age 20-74 years with undiagnosed NIDDM have fasting hyperglycemia (Ó140 mg/dl) (Harris *et al.,* 1985). Other studies have also found that as many as 80% of diabetes cases discovered in population screening by OGTT have EPG < 140 mg/dl (Clement *et al.*, 1993).

Sensitivity is somewhat lower in women compared with men, but there is little effect of age or ethnicity. Body mass index (BMI) < 23 is associated with considerably lower sensitivity with no difference between the two higher BMI categories (23-26.9 and Ó 27). However individuals with BMI < 23 constitute only about 10 % of all NIDDM cases. Hypertension, treated or untreated, has no consistent effect on sensitivity. In summary variations in sensitivity by age, sex, ethnic group, BMI or blood pressure status appear to be too small to have practice implications regarding the effectiveness of screening by FPG (Modan and Harris, 1994).

Screening by other methods

Other methods of screening for undiagnosed NIDDM has been evaluated and found to be inadequate (Harris and Modan, 1994**).** Glycosylated haemoglobin has the same advantage as FPG requiring only one blood sample and minimal patient cooperation, and in addition is not affected by time of day or recent food intake. Measurement of casual or random blood glucose or urine glucose are not acceptable screening methods because these cannot be standardized with regards to risk of having diabetes or developing its complications, due to considerable

fluctuations of blood and urine glucose level according to the interval since the preceding meal, the unstandardized content of the meal, and the often unknown renal threshold for glycosuria.

2.7 Management and treatment of *Diabetes mellitus*

2.7.1 Pharmacologic interventions

2.7.1.1 Use of oral hypoglycemic/ antidiabetic drugs

Diabetes mellitus is a chronic disease that requires life-long pharmacological and non-pharmacological management to prevent complications such as cardiovascular disease, retinopathy, nephropathy and neuropathy (Qaseem, 2012**).** In the United States of America, eleven classes of medications are approved for management of *Diabetes mellitus*, these include eight oral agents such as-biguanides, sulfonylureaôs, meglitinides, thiazolidinediones (glitazones), alpha glucosidase inhibitors, DPP-4 inhibitors, bile acid sequestrants, dopamine-2 agonist and 3 injectable agents such as-GLP-1 receptor agonists (Incretins), amylin analogues and insulin (Alexander, 2008**).** The 18th WHO expert committee on the selection and use of essential medicines in 2011 requested a review of the current oral hypoglycemic medicines for use in the adult to determine if updates to the EML are needed (WHO, 2011). Currently the EML contains two oral hypoglycemics, glibenclamide (sulfonylurea) and metformin.

2.7.1.1.1 Sulfonylurea

The hypoglycemic effect of sulfonylureas was first discovered in France during World War II as a chance finding in the course of investigations concerning the antibiotic properties of modified sulfonamides.

Since the early 1950s sulfonylureas, mainly tolbulamide and chlorpropamide have been used extensively in the treatment of diabetes. The incidence of adverse reactions is low, with a total rate for all side effects estimated at 3.2 percent for tolbutamide and 6 percent for

chlorpropamide (Shen and Bressler, **1977**). The most frequently described significant side effects are haematologic (agranulocytosis, bone marrow aplasia, red cell aplasia) and gastrointestinal (nausea, vomiting, heart burn, abnormal liver function tests, Jaudice). Other described effects include cutaneous reactions (rashes, pruritis), vasomotor effects (disulfiram-like reaction to alcohol-most commonly seen with chlorpropamide) possible hypothroidism, and dilutional hyponatremia with water intoxication (due to the anti-diuretic action of chlorpropamide and perhaps tolbutamide) (Pannekoek, 1975).

Mechanism of actions of sulfonylurea drugs

During the late 1950s and early 1960s most studies seemed to indicate that the primary action was an increase in insulin release. More recently, however, a large body of clinical investigative data has caused serious doubts on the significance of the role that insulin-secretary effects of sulfonylureas play in their chronic anti-diabetic action.

Sulfonylureas and glucagon secretion

A decrease in glucagon secretion by the sulfonylureas could explain their anti-diabetic action. Early studies in which sulfonylureas failed to lower the blood glucose in alloxan-diabetic animals were used as evidence to rule out an effect of these agents on glucagon secretion. More recent studies, both *in vivo* and *in vitro,* have evaluated the effects of sulfonylureas on glucagon secretion by measurement of glucagon with radioimmunology assay techniques. While studies with duck pancreas have shown sulfonylurea-induced suppression of glucagon secretion (Salmols *et al.,* 1969), those with rat pancreas show either stimulation or inhibition, depending on the experimental conditions (Grodsky *et al.*, 1977). There is no good evidence that acute or chronic sulfonylurea therapy alters glucagon secretion in normal subjects or patients with

diabetes mellitus (Peks *et al.,* 1972). Thus, it is unlikely that the anti-diabetic action of sulfonylureas is related to an alteration in glucagon secretion.

New sulfonylurea (third generation)

Glimeperide, a third generation sufonylurea binds to a 65kd protein of the putative sulfonylurea receptor different from the 140 kd protein targeted by other sulfonylurea (Kramer *et al.*, 1994). It has a three fold faster rate of association and nine fold faster rate of dissociation than glibenclamide (Kramer *et al.*, 1994) and thus has rapid onset and prolonged duration of action, permitting once daily administration (Draeger, 1995). Though, its initial action is stimulation of insulin secretion, it has also an insulin-mimetic effect in peripheral tissues possibly mediated by GLUT-4 recruitment (Muller and Wied, 1993). The extra pancreatic effects may explain lesser degree of stimulated hyperinsulinaemia. Unlike glibenclamide, this drug prevents post-exercise insulin release, thereby decreasing the risk of hypoglycaemia (Draeger, 1995). It is absorbed completely in either fasting or fed state. It does not accumulate in the body with reducing renal function (Up to GFR 10ml/min) and its hydroxyl metabolite has negligible effects on blood glucose and is excreted equally by the liver and kidney. Hence, it is safe in renal failure and in the elderly (Draeger, 1995). It does not exhibit any drug interaction and because of its poor binding to extrapancreatic, myocardial and vascular system ATP dependent K^+ channels, the risk of coronary vasoconstriction and adverse cardiovascular events are reduced in comparison to other sulfonylureas (Smits and Thieri, 1995). On a weight for weight basis, glimeperide is the most potent sulfonylurea with suggested dose between 1-6 mg once daily but dose up to 8mg may give additional glucose lowering effect (Smits and Thieri, **1995**).

The following Table summarizes the names of first, second and third generation sulfonylurea their structures, dosage range and tablet.

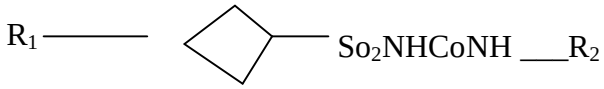

Table 4: First, second and third generation sulfonylureas

First generation

	NAME	R_1	R_2	Dosage Range(mg)	Tablet Size (mg)
1.	Tolbutamide	CH_3-	-$(CH_2)_3CH_3$	500-3000	500
2.	Chlorpropamide	CC-	-$(CH_2)_2CH_3$	100-500	100, 200
3.	Tolazamide	CH_3-	- 	100-750	100, 200
4.	Acetohexamide	CH_3CO-	- 	500,- 1,500 200, 500	

Second generation

5.	**Glibenclemide**			**2.5-20**	**5**
6.	**Glipizide**			**2.5-45**	**5**
7.	**Glibornride**	**CH_3**		**12.5-100**	**12.5**

Third generation

8.	**Glimeperide**			**1-6**	

(Adapted from The Academy of Dental Learning and OSHA Training. www.ada.org/cerp)

2.7.1.1.2 Biguanides

Biguanides were banned in the United States during the 1970ôs because they were linked to lactic acidosis. A safer biguanide, metformin has been released (brand name Glucophage) and the risk of lactic acidosis appears to be minimal. These drugs work by decreasing the amount of glucose release from the liver

Metformin is the first-line drug treatment for type 2 diabetes. According to national and international guidelines, metformin is the recommended first line oral therapy for the treatment of type 2 diabetes (Inzucchi *et al.*, 2012). This is due to several factors including the impressive safety record of the drug, having been in clinical use for over 50 years and the fact that metformin treatment is weight neutral. In addition, there are likely to be other beneficial effects including reduction in cardiovascular disease and mortality compared with non-intensive treatment and a possible reduction in cancer incidence which has been seen in some (Noto *et al.*, 2012) but not in all patients (Van Staa *et al.*, 2012). Chemically, biguanides such as metformin are composed of two guanides groups joined together with the loss of ammonia. Antihyperglycaemic effects have been observed in response to many but not all, guanidine-containing compounds. For metformin, these effects are uniquely dissociated from toxicity.

The liver is the main site of action of metformin

Metformin is not metabolized and is excreted in the urine and bile in an unmodified form. The pharmacokinetics of metformin is largely determined by its active transport by key organic cation transporters. Members of this transporter family (Koepsell *et al.*, 2007) are involved in action transport across the gut epithelum and hence determine rates of absorption of plasma membrane monoamine transporter (PMAT) and organic cation transporter (OCT3); they transport metformin into hepatocytes (OCTI) and from hepatocytes into the bile (multidrug and

toxic compound extrusion (MATE) and finally into the renal tubular epithehal cells (OCT2) and into the renal tuble (MATE2) (Rena *et al.*, 2012).

Although metformin exerts its major effects through inhibition of hepatic glucose production, enhanced glucose disposal has also been described. Some early studies suggested that metformin exerts its insulin-sensitizing effect (Bailey and Puah, 1986) and or promotes glucose transport independently of the insulin receptor-mediated proximal signaling pathway in skeletal muscle (Turban *et al.,* 2012). Other biguanides are phenformin and buformin which have been withdrawn from market for their toxic effects.

Table 5: Structures of biguanides

S/No	Name	Chemical name	Chemical structure
1	Metformin	Dimethyl biguanidine	2	Buformin	A butyl derivative of biguanide	3	Phenformin	A phenethylated biguanidine	
Source: Tonascia and Meinert, (1986**)**

The most common side effect of biguanide is diarrhoea and dyspepsia, occurring in up to 30% of patients. The most important and serious side effect is lactic acidosis. Metformin is therefore contraindicated in renal insufficiency. Renal functions should be assessed before starting metformin treatment. Phenformin and buformin are more prone to cause acidosis than metfomin, therefore they have been practically replaced by it. However, when metformin is

combined with other drugs (combination therapy) hypoglycemia and other side effects are possible.

2.7.1.1.3 Thiazolidinedione (TZD)

They are also known as glitazones and are a class of medication or drugs used in the treatment of diabetes mellitus type 2. They were introduced in the late 1990s.

Thiazolidinediones are used clinically to reduce blood glucose, triglyceride and free fatty acid levels in animal models of insulin resistance type 2 diabetes and in humans with these conditions (Diamart and Heine, 2003).

Mechanism of action

Thiazolidinediones act by activating PPARs (peroxisome proliferator-activated receptors), a group of nuclear receptors, with greatest specificity for PPARɔ (gamma). The endogenous ligands for these receptors are free fatty acids (FFAs) and eicosanoids. When activated, the receptor binds to DNA in complex with the retionoid X receptor (P XR), another nuclear receptor, increasing transcription of a number of specific genes and decreasing transcription of others (Mangelsdorf *et al.,* 1995). The PPARɔ can be activated by naturally occurring compounds such as the long chain fatty acid derivative 15-deoxy-æ (12, 14)-prostaglandin (Forman *et al*., 1995; Kliewer *et al.,* 1995). In addition to TZDs, the N- 9-fluorenylmethyloxy carbonyl leucine derivative, FMOC- L- Lucine (F-L- Len), is another chemically distinct synthetic ligand of PPARɔ that also shows insulin-sensitizing action *in vivo*. Although some effect of TZDs are PPARɔ, independent, this nuclear receptor is the major functional receptor that mediates the pharmacological actions of these drugs, because their clinical potency correlates closely with their respective capacity to bind to this receptor (Willson *et al*., 1996**).**

Fat redistribution

One result of PPARɔ activation is enhanced differentiation and proliferation of preadipocytes into mature fat cells, particularly in non-visceral (peripheral/subcutenous) fat depots. There is an upregulation of enzymes/transporters in adipocytes to facilitate their uptake of fatty acids (e.g increase in lipoprotein lipase, fatty-acid transporter 1 and glycerol kinase) (Lee *et al.,* 2003). It is notable and probably important, that most of these consequences of PPARɔ stimulation are not seen in visceral adipocytes, even though; these cells have abundant PPARɔ receptors. Visceral adipocytes are also metabolically quite different to peripheral adopocytes in other ways. For example, they are less responsible to insulin and more responsive to catecholamines. Increased fatty acid storage in subcutaneous adipocytes results in a ñLipid stealò phenomenon, leading to lower circulating fatty acids and reduced concentrations of triglycerides in musle and liver (Gurnell *et al.,* 2003). Studies in animal and humans have shown that TZDs only improve insulin action (and glycemic control in diabetes) in the presence of insulin resistance (Oakes *et al.,* 1994). This may be explained by the fact that the effects of these drugs on lipid redistribution are only beneficial if there is excess tissue lipid availability. The ñLipid stealò effect of TZDs may therefore be a major contributor to improved insulin action in muscle (enhanced glucose utilization) and liver (reduced hepatic glucose output), as the direct effects of PPARY stimulation in muscle and liver are unclear. The potential role of the TZDs in reducing hepatic lipid content in non-alcoholic steartohepatitis is still under investigation. The TZDs do not increase insulin. On the contrary, they reduce insulin level acutely, which may be a consequence of improved insulin sensitivity and or reduced circulating fatty acid (as fatty acids stimulate insulin secretion). In the longer term, TZDs arrest the decline in ɓ-cell function that occurs in type2 diabetes perhaps by protecting ɓ-cell from lipotoxicty (Parulkar *et al.,* 2001)

Other biological effects

The effects of the thiazolidinediones on lipid concentrations tend to increase while triglyceride concentrations decrease. Although, LDL cholesterol concentrations may increase initially, this effect lessens over time and particles are now larger and more buoyant (Gurnell *et al.*, 2003). The outcomes of ongoing large clinical trials may clarify the effect of TZDs on cardiovascular risk. Proglitazone has some PPARŬ activity, which may account for the data suggesting a more favourable effect on triglyceride and LDL cholesterol levels (Parulkar *et al.,* 2001). Another reported effect, which may not be mediated by PPARↃ, is a degree of anti-inflammatory activity and reduction in macrophage function (Gurnell *et al*., 2003). Limited evidence suggests also that the thiazolidinediones may improve insulin resistance and ovulatory function in women with polycystic ovary syndrome (Parulkar *et al.,* 2001).

Pharmacokinetics and drug interactions

The thiazolidinediones are rapidly absorbed and reach peak concentrations within a few hours (Mudaliar and Henry, 2001). Steady state is usually reached within one week, but perhaps because of the importance of fat redistribution, the full benefit may take 4-12 weeks to become evident. Rosiglitazone and proglitazone are strongly protein bound in the circulation, predominately to albumin (Mudaliar and Henry, 2001). No significant drug interactions have been reported with the thiazolidinediones, but it should be noted that in combination with the sulfonylureas, hypoglycaemia may occur due to the combination of enhanced insulin sensitivity (Thiazolidinediones) and enhanced insulin secretion (Sulfonylureus). Thiazolidinediones are metabolized by cytochrome p450 2 CB (and by CYP3A4 for pioglitazone) but at conventional doses apparently do not affect the activity of those enzymes. Caution should still be exercised when using TZDs in combination with drugs metabolized by these enzymes.

Members of thiazolidinedione

The members are derivatives of the parent compound, thiazolidinedione and they include:

1. **Rosiglitazone (Avandia):** It was put under selling restrictions in US and withdrawn from the market in Europe due to some studies suggesting an increased risk of cardiovascular events. Upon re-evaluation of new data in 2013, the FDA lifted the restriction
2. **Proglitazone (Actos):** France and Germany may have suspended its sale after a study suggested the drug could raise the risk of bladder cancer.
3. **Lobeglitazone (Duvie):** Approved for use in Korea
4. **Troglitazone (Resulin):** It was withdrawn from the market due to an increased incidence of drug-induced hepatitis

Other members of this class include

5. Netoglitazone
6. Rivoglitazone
7. Ciglitazone

Uses

The only approved use of the thiazolidinediones is in *Diabetes mellitus* type 2. It is being investigated experimentally in polycystic ovary syndrome (PCOS), non-alcoholic steatohepatitis (Belfort *et al*., 2006), Psoriasis (Krentz & Friedmann, 2006) autism (Borris, 2007), ovarian hyper stimulation syndrome (by VEGF inhibition in granulose culb (Shah *et al.,* 2010), lichen planopilaris and other conditions. There are some indications that thiazolidinediones provide some degree of protection against the initial stages of breast carcinoma development.

Side effects and contraindications

The main side effect of all thiazolidinediones is water retention, leading to edema. It occurs in less than 5% of individuals, but it is a big problem. Significant water retention, will lead to a decompensation of potentially previously unrecognized heart failure. Therefore, thiazolidinediones should be prescribed with both caution and patient warnings about the potential for water retention/weight gain especially in patients with decreased ventricular function

Though older studies suggested there may be an increased risk of coronary heart disease and heart attacks with rosiglitazome, proglitazone treatment, in contrast, has shown significant protection from both micro and macro-vascular cardiovascular events and plague progression that aided extensive media coverage led to a substantial decrease in rosiglitazone use (Nissen *et al.,* 2008**).** In November 2013, the FDA announced it would remove the usage restrictions for rosiglitazone in patients with coronary artery disease. Preliminary data from a 10- year epidemiological study from Takeda pharmaceutical company indicated a possible link between proglitazone (Actos) and bladder cancer. The findings promoted the FDA to order safety reviews for the drug in September, 2010.

2.7.1.1.4 Meglitinide

The meglitinide analogues are insulinotropic agents introduced in 1995 and approved for clinical use in adults with type 2 diabetes mellitus in 2000. They are secretagogue molecules with more rapid anti-hyperglycemic action and a shorter duration than sulfonylureas, thus providing better control of postprandial hyperglycemia and reducing the risk of late hypoglycaemias (Dornhorst, 2001; Landgraf, 2000**).**

Repaglinide

Repaglinide was the first meglinide analogue approved for clinical use in adults with Type 2 DM. Repaglinide in the S(+) enantiomer of 2- ethoxy-4-(2-((3-methyl-1-(2-(1-piperidinyl)-butyl) amino)-2-oxoethyl) benzoic acid with a molecular weight of 452.6 Da.

The mechanism of action is similar to sulfonylureas, but repaglinides exhibits distinct pharmacological properties in structure, binding profile, duration of action and mechanism of excretion (Culy and Jarvis, 2001). Like the sulforylureas, the insulinotropic action of repaglinide is mediated via adenosine triphosphate (ATP)- dependent potassium channels. Repaglinide stimulates insulin secretion by blocking ATP-dependent potassium channels (KATP) of the pancreatic beta cell, where inhibition of KATP channels results in membrane depolarization and calcium influx through voltage-gated calcium channels. These events lead to an increase in intracellular calcium and subsequent exocytosis of insulin- containing granules.

Repaglinide binds to the sulfonylurea receptor SURI and it seems to have also a separate distinct binding site on ɓ- cells co-incubated with PPP (3- (3 hydnetyphenyl)- N- (1-propy 1) piperidine), a pharmacological tool to differentiate between the two different binding sites (Fuhlendorff, 1998). Moreover, molecular studies have shown that the binding site of repaglinide is different from that of glibenclamide and nateglinide (Gromada, *et al.,* 1995**).**

Nateglinide

Nateglinide is a (N- [c trans-4-isopropyl-cyclonexyl)- carbonyl]-D- Phenylalanine A-4166) phenylalanine derivative. Like repeglinide, nateglinide also binds competitively to SUR, inhibiting KATP channels and stimulating insulin secretion, but the pharmacodynamic properties of this molecule are unique in several aspects (HU, 2002). Comparative preclinical studies *in vitro* indicate that nateglinide inhibits KATP channels more rapidly, and with a shorter duration

of action than glibenclamide, glimeperide and repaglinide, and shows a greater degree of specificity for sulfonylurea receptor (SuR), over SuRz, as compared with glibenclamide and repaglinide. Also the half life of nateglinide on the receptor is approximately 2X, much shorter when compared to that of repaglinide, which is 23min. In addition, the dissociation from the receptor is estimated to be 90X faster than that of repaglinide, indicating a very short on-off effect of nateglinide on insulin release (Hu, 2002).

Foley *et al* have demonstrated a sort of ñglucose-sensitizing propertyò of nateglinide in *in vitro* experiments on rat ɓ- cells. In fact, unlike glibenclamide and repaglinide, the potency of nateglinide increases in the presence of glucose. The inhibition of KATP current is enhanced 16 fold when the glucose concentration is raised from 3 mmol/L to 16 mmol/L. Interestingly, the glibenclamide potency is much reduced under the conditions where as the potency of repaglinide is enhanced 4- fold, which could explain the low incidence of hypoglycaemia (Hu, 2002)
Moreover, phamacodynamic studies in patients with Type 2 DM have demonstrated that the administration of nateglinide (prior to meals) induces early phase insulin secretion and significantly reduces post-prandial hyperglycaemia in a dose-dependent manner. Interestingly, insulin secretion was significantly greater when nateglinide was taken before a meal compared to neteglinide given in the fasted state or in response to just the meal (Keelson *et al.,* 2000).

Pharmacokinetic properties

Repaglinide is rapidly absorbed after oral administration. The peak plasma concentration is reached 30-60 min after administration, plasma levels decrease rapidly and the drug is eliminated within 4-6 hrs. Its absorption is not affected by food, bioavailability is 63% and the half-life is ~ 1 hour (Hatorp et *al.,* 1999)

Repaglinide has a small volume of distribution and is highly bound (more than 98%) to plasma albumin. Repaglinide is metabolized by the liver cytochrome P456 (CYP_3A_4) and eliminated rapidly through the bilary tract, without apparent accumulation in the plasma after a multiple dose (Hatorp, 2002).

Nateglinide

Nateglinide is rapidly absorbed after oral administration from the gastro intestinal tract in a dose-dependent manner and the bioavailability of the drug is approximately 72% (Weaver *et. al.,* 2001). The optimal time of oral administration of nateglinide is before the meal; infact absorption is more rapid when the drug in administered 0-30 min before meals (Luzio *et. al.,* 2001). Peak plasma concentrations are achieved within 1hr and the half-life is 1.8 h because it is rapidly eliminated from plasma. This short elimination half-life ensures no drug accumulation at any dose level. Nateglinide is metabolized mainly via the hepatic CYP2C9 and CYP3A4 isoenzymes of cytochrome p450 and eliminated primarily by the kidney. Twenty percent of a nateglinide dose is eliminated unmodified in the bile and 10% in the urine (Weaver *et al.*, 2001). Neteglinide is also extensively bound to plasma proteins (98%) and has a relatively small volume of distribution (Weaver *et al.,* 2001).

Indications and usage

Neglitinide analogues, acting on the pancreatic ϐ-cells, mimic some how the early rise of insulin secretion after meal ingestion and reduce postprandial hyperglyceamia (Landgraf, 2000). Clinical trials of nateglinide and repaglinide have shown efficacy and safety as monotherapy and in combination therapy in patients with T2DM. Both nateglinide and repaglinide have good safety profile. Moreover, repaglinide is eliminated mainly via-non renal routes and can therefore

be administered to patients with mild to moderate renal insufficiency and or in whom one of the other second line anti-hyperglycemic drugs is contraindicated (Marbury *et al*., 2000)

2.7.1.1.5 Incretin mimetics

The incretin effect describes the phenomenon that oral glucose leads to a greater insulin response than an isoglycaemic intravenous glucose load (Nauck *et al.,* 1986). There are two major incretins:

1. Glucose depedent insulinotropic polypeptide (GIP)
2. Glucagon- like peptide 1 (GLP-1)

Glucagon- like peptides are preserved in patients with type-2 DM. GLP-1 is a product of the glucagon gene, which is expressed in pancreatic Ŭ- cells and in L- cells, located mostly in the lower small intestine and colon. GLP-1 concentrations increase as early as 5 to 10 minutes following ingestion of carbohydrates and lipids, well before the nutrients pass into the lower gut where most L- cells are located (Eissele *et al.,* 1992). Once released from L-cells, GLP-1 is rapidly metabolized by a widely distributed serine protease, DDP-4, resulting in a half-life of 1 to 2 mins in the circulation. DPP-4 which is located at endothelial cells as well as in soluble form in plasma, cleaves the two N-terminal amino-acids from GLP-1, causing a substantial loss of insulinotropic activity (Vahl *et al.*, 2003). GLP-1 stimulates insulin secretion from the beta cells and inhibits glucagon secretion from alpha cells. Both actions occur in a glucose-dependent manner and lead to a normalization of postprandia and fasting hyperglyceamia (Drucker, 2006). In the gasterointestinal tract, GLP-1 has a direct effect on motility and slows gastric emptying. This effect contributes to normalization of postprandial hyperglycaemia and explains why long-term treatment with GLP-1 receptor agonists leads to weight loss (Drucker, 2006). Under

hypoglycaemic conditions, the counter-regulation by glucagon is not affected and insulin secretion is not stimulated and, therefore GLP-1 does not elicit hypoglycemia (Drucker, 2006).

Type 2 DM and incretin- based therapy

The incretin-based therapies after a good alternative choice to the established antidiabetic compounds due to their satisfying antihyperglycemic efficacy, their lack of risk of hyperglycaemia and their positive effects on body weight. In order to utilize GLP-1 action for T2DM, two options are presently available

1) GLP-1- receptor agonist (or GLP-1 mimetics) as injectable compounds
2) DPP-4 inhibitors as orally active substances

GLP-1 receptor agonists

a)Exanatide: Exenatide is the synthetic form of exendin- 4, a peptide first discovered in the saliva of the gila monster (*Heloderms suspectum*) in 1992. It has a 53% amino acid sequence homology to human GP-1 and is a GLP-1 receptor agonist (Eng, 1992). It is administered subcutanously once daily. It has a prolonged half life in comparison to native GLP-1 of approximately 3.5 hours. After subcutenous injection, sufficient plasma concentrations are reached 4-6 h (Kolterman *et al.,* 2003). In clinical studies, exenatide lowered the HbA_{1c} by 0.8-1.1% (Defronzo *et al*., 2005). Exenatide in combination with metformin (Kendall *et al.,* 2005**),** sulfonylurea (Defronzo *et al*., 2005) or both (Buse, *et al.,* 2004) resulted in significant mean HbA_{1c} reductions from baseline ranging from 0.77% to ï 0.86%. Patients also had statistically significant reductions in mean body weight from baseline (-1.6kg to- 2.8kg). Comparative

studies with insulin showed that effects of exenatide on glycaemic parameters are comparable to the improvement seen with insulin therapy (Heine *et al.,* 2005; Gallwitz, 2006).

Severe hypoglycemic events were only observed in exanatide- treated patients who had received combination therapy with sulfonylurea. For this reason, a reduction in the dosage of sulfonylurea should be considered when initiating exanatide therapy. In the comparative studies, comparing exanatide with insulin treatment, the incidence of nocturnal hypoglycaemic events was lower in the exenatide- treated patients (Barnett, 2007).

b) Liraglutide

Liraglutide is the first human GLP-1 analogue. It has two modifications in the amino acid sequence of native GLP-1 and an attachment of a fatty acid side chain to the peptide. It is injected subcutaneously once daily (Agerso *et al*., 2002). Liraglutide lowers blood glucose, body weight and food intake in animal model (Sturis *et al*.,2003). In clinical studies in approximately 4,200 Type 2 DM patients, liraglutide was efficacious and safe (Marre *et al.,* 2009; Zinman *et al*., 2009).

DPP-4 inhibitors

a) Sitagliptin

Sitagliptin was the first DPP-4 inhibitor approved for the T2DM treatment. The recommended dose of once-daily oral sitagliptin is 100 mg. At this dose, sitagliptin can inhibit ~80% of endogenous DPP-4 activity over a 24- hour period (Herman *et al.,* 2005).

b) Vildagliptin

Vildagliptin also acts by inhibiting circulating DPP-4 activity. It is available as a 50mg twice daily in combination with metformin, sulfonylurea or pioglitazone. Vildagliptin has been

studied as monotheraphy (Dejager *et al.,* 2007) and in combination with other oral anti-diabetic agents (Ahren, 2008).

2.7.1.1.6 Alpha- glucosidase inhibitor

They are oral anti-diabetic drug used for *Diabetes mellitus* type2 that work by preventing the digestion of carbohydrates. They are a class of drugs known as ñstarch blockersò. They slow absorption of certain carbohydrates in the gastrointestinal tract.

Drugs that belong to this class include

1) Acarbose (precose)
2) Miglitol (glyset)
3) Voglibose (volix)
4) Emiglitate

The guidelines issued by the American Diabetes Association suggest that the expected decrease in HbA_{1c} would be between 0.5% and 0.8% when this drug is used alone (ADA, 1997).

2.7.1.2 Insulin therapy

Normally produced by the ɓ-cells of the pancreas, insulin assists in the diffusion of glucose into the cell. When there is no insulin (Type 1 diabetes), glucose cannot enter the cell and be converted into energy. For individuals who do not produce insulin, insulin injections are necessary to balance the amount of glucose in the blood. Insulin cannot be taken orally because stomach acid will destroy it before it is effective (Dorman *et al.,* 1995).

Table 6: Common subcutaneous insulin pharmacodynamics

S/n	Action	Type	Onset	Peak	Duration
1	Rapid	Aspart (Novolog) Lispro (Humalog) Glulisine (Apridra)	0.24hours	0.5- 1.5hrs	Duration 3-6 hors
2	Short	Regular	30mins	2.5- 5 hrs	6-8 hrs
3	Intermediate	NDH	1hr	3-6 hrs	11-16 hrs
		Lente	2hr	4-8 hrs	12-18 hrs
4	Long acting	Ultralente	4-6 hrs	12-16h	Up to 3hrs
		Glargine (lantus) 70/30	1-2 hrs	peakless	24hrs
5	Mixed insulin intermediate short acting	(a) 70% NPH/ 30% regular	30 mins	1-4 hrs	4-30 hrs
		(b) 50/50: 50% NPH/50% Regular	30 mins		4-15hrs
6	Intermediate + Rapid acting	Huamalog mix 75/25 75% NPL/ 25% Lispro	0.25hrs	1-4hrs 05-6.5 hrs Dual peaks	24hrs
7	Intermediate + rapid acting	Novolog mix 70/30: 70% NPA 130% Aspart	0.25hrs	1-4 hrs dual peaks	24hrs

2.7.1.3 Injectable amylin analogue

Amylin agonist analogues slow gastric emptying and suppress glucagon. They have all the incretins actions except stimulation of insulin secretion. As of 2007, pramlintide were the only clinically available amylin analogue. Like insulin, it is administered by subcatenous injection. The most frequent and severe adverse effect of pramlintide is nausea, which occurs mostly at the beginning of treatment and gradually reduces. Typical reductions in HbA_{1c} values are 0.5-1.0% (Buse *et al*., 2004)

Amylin is a peptide hormone that is co-secreted with insulin from the pancreatic ɓ-cell and is thus deficient in diabetic people. It inhibits glucagon secretion, delays gastric emptying, and acts as a satiety agent.

2.7.1.4 Glycourics

Sodium glucose co-transport SGLT-2 inhibitors block the re-uptake of glucose in the renal tubules, promoting loss of glucose in urine. This causes both mild weight loss, and a mild reduction in blood sugar levels with little risk of hypoglycaemia (Dietrich *et al*., 2013). Urinary tract infection is a common side effect. Example of SGLT-2 inhibitors include

1. Canagliflozin
2. Dapagliflozin
3. Empagliflozin

2.7.1.5 Medicinal plants with antidiabetic activity

The following plants are known for their hypoglycemic properties;

1.*Abelmoschus moschatus* Medik (Malvaceae),

2.*Acacia arabica* (Lam) Wild. (Mimosaceae),

3.*Achyranthes aspera* L (Amaranthaceae)

4.Achyrocline satureioides (Less) DC (Asteraceae)

5. *Acosmium panamense* Schott. (Leguminosae)

6. *Aegle marmelose* (L) Corr. (Rutaceae)

7. *Agrimony eupatoria* L. (agrimony) (Rosaceae)

8. *Ajuga iva L. Schreberr* (Medit) (Lamiaceae)

9. *Allium cepa L*. (onion): (Liliaceae)

10. *Allium sativum* L. (garlic): (Liliaceae)

11. *Aloe vera* (L) Burm.(Asphodelaceae)

12. *Andrographis paniculata* Burm. (Acanthaceae)

13. *Annona squamosa* L (Annonaceae)

14. *Artemisia herba-alba* Asso (Med).(Asteraceae)
15. *Artemisia dracunculus* L. (Asteraceae)
16. *Astragalus membranaceus Bunge* (Fisch.): (Leguminosae)
17. *Averrhoa bilimbi* L (Oxalidaceae)
18. *Azadirachta-indica A*. Juss. (Meliaceae)
19. *Bauhinia candicans* Benth (Leguminosae)
20. *Bauhinia forficate* Link. (Caesalpinaceae)
21. *Bidens pilosa* L (Asteraceae)
22. *Biophytum sensitivum* (L) DC. (Oxalidaceae)
23. *Bixa orellana* L. (Bixaceae)
24. *Brassica nigra* (L) Koch (Brassicaceae)
25. *Bryonia alba* L.(Cucurbitaceae)
26. *Bumelia sartorum* Mart. (Sapotaceae)
27. *Caesalpinia bonducella* (L) Roxb. (Caesalpinaceae)
28. *Cajanus cajan* (L) Millsp. (Papilionaceae)
29. *Casearia esculenta* Roxb. (Flacourtiaceae)
30. *Cassia auriculata* L.(Caesalpinaceae)
31. *Catharanthus roseus* (L)G.Don.(Apocynaceae)
32. Chamaemelum nobile (L) All. (Asteraceae)
33. *Cichorium intybus* L.(Asteraceae)
34. *Clausena anisata* (Willd) Benth. (Rutaceae)
35. *Coriandrum sativum* L (Apiaceae)
36. *Cuminum cyminum* L (Apiaceae)

37. *Cuminum nigrum* L (Apiaceae)

38. *Cyamopsis tetragonoloba* (L) Taubert.(Papilionaceae)

39. *Dioscorea dumetorum* (Kunth) Pax.(Dioscoreaceae)

40. *Eclipta alba* (L) Hassk. (Asteraceae)

41. *Emblica officinalis Gaertn*. (Euphorbiaceae)

42 *Enicostema littorale blume* (Gentianaceae)

43. *Ficus bengalensis* L. (Moraceae)

44. *Garcinia kola Heckel* (W & C Afr)((Clusiaceae)

45. *Gongronema latifolium Endl*. (Asclepiadaceae)

46. *Helicteres isora* L., As.(Sterculiaceae)

47. *Hypoxis hemerocallidea* conn Corm (Africanpotato) (Hypoxidaceae)

48. *Inula racemosa* Hook.f.(Asteraceae)

49. *Lagerstroemia speciosa* (L) Pers.(Lythraceae)

50. *Lepidium sativum* L. (Brassicaceae)

51. *Mangifera indica* L.(Anacardiaceae)

52. *Momordica charantia* L. (Cucurbitaceae)

53. *Morinda lucida* Benth.(Rubiaceae)

54. *Myrcia uniflora* Barb., Rods.(Myricaceae)

55. *Nigella sativa* L (Ranunculaceae)

56. *Ocimum sanctum* L. (Lamiaceae)

57. *Origanum vulgare* L. (Lamiaceae)

58. *Otholobium pubescens* L. (Papilionaceae)

59. *Paeonia lactiflora* Pall.(Paeoniaceae)

60. *Panax ginseng* C. Meyer. (Araliaceae)

61. *Phyllanthus amarus* Schum & Thonn. (Euphorbiaceae)

62. *Psidium guajava* L. (Myrtaceae)

63. *Pterocarpus marsupium* Roxb.(Papilionaceae)

64. *Retama raetam* (RR) (Forssk) Webb. (Papilionaceae)

65. *Salacia reticulate* W. (Celastraceae)

66. *Spergularia purpurea* (SP) (Pers) G, Donf.(Caryophyllaceae)

67. *Suaeda fruticosa* (SF) Euras (Chenopodiaceae)

68. *Syzigium cumini* (L) Skeels.(Myrtaceae)

69. *Tamarindus indica* L. (Caesalpinaceae)

70. *Telfaria occidentalis* Hook. (Cucurbitaceae)

(Kavishankar *et al.*, 2011)

2.7.2 Non-pharmacologic intervention

2.7.2.1 Excercise

For decades, exercise has been considered a cornerstone of diabetes management along with diet and medication. Exercise is a subset of physical activity planned, structured and repetitive bodily movement performed to improve or maintain one or more components of physical fitness while physical activity in bodily movement produced by the contraction of skeletal muscle that requires energy expenditure in excess of resting energy expenditure (Wasserman and Cherrington 1996).

Endogenous glucose production

Endogenous glucose production (EGP) is closely coupled to the increase in muscle glucose uptake during moderate exercise. Studies conducted in animal models and human subjects have

defined the importance of insulin and glucagon in the stimulation of EGP during light and moderate exercise (Wasserman and Cherrington, 1996). Glucagon also stimulates hepatic amino acid metabolism (Krishna *et al.,* 2000) providing precursors for gluconeogenesis and energy to fuel it. The decrease in insulin during exercise is necessary for the full glycogenolytic response (Wasserman and Cherrington 1996).

In contrast, in very intense aerobic exercise (> 80% of V_{O2}max), the catecholamines likely play important role. In this situation, nor-epinephrine and epinephrine levels rise as much as 15 fold from baseline, and glucose production in young fit subjects rises about 7-fold during exercise (Marliss *et al.,* 1995). In normal subjects, plasma insulin doubles soon after the end of a very intense exercise session, restoring glycemia to baseline within an hour (Marliss *et al.,* 1995**).** In contrast in type I diabetics in which endogenous insulin cannot increase, hyperglycemia after a very intense exercise lasts at least several hours (Sigal *et al.,* 1996; Purdon *et al.,* 1993). Type 2 diabetic patients with a mild to moderate elevation in glucose levels may experience a fall in glucose during exercise due to impaired endogenous glucose output. This population when maintained on diet therapy alone or diet and sulfonylurea therapy with post absorptive plasma glucose in excess of 200 mg/dl and normal basal insulin, shows a fall in glycemia of 50 mg/dl during a 45-min exercise bout (Minuk *et al.,* 1981). High-intensity intermittent exercise performed in postprandial type 2 diabetic subjects has the same plasma glucose and insulin lowering effect as moderate-intensity exercise of equivalent caloric requirement (Larsen *et al.,* 1997).

Fat metabolism

Moderate exercise is associated with an approximately 10 fold increase in fat metabolism. This is due to increased energy expenditure coupled with greater fatty acid

availability. The increase in fatty acid availability is due both to an increase in lipolysis and decreased re-esterification of Non-essential Fatty Acid (NEFA) to triglycerides (Wolfe *et al.,* 1990). Acute NEFA release from adipose tissue is regulated primarily by the actions of insulin and the catecholamines when the exercise-induced fall in insulin is prevented; the increase in NEFA levels is prevented (Wasserman and Cherrington, 1996). Metabolism of fats during exercise is quantitatively different in obese type 2 diabetic subjects in relation to healthy subjects. In this population, utilization of plasma free fatty acid is reduced, while intramuscular triglyceride untilization is increased (Blaak *et al.,* 2000). Interestingly, lean type 2 diabetic patients do not have this adaptation to exercise (Borghouts *et al.,* 2002).

Muscle glycogenolysis

Glycogen breakdown is regulated by glycogen phosphorylase. It is interesting that although muscle glycogenolysis increase with increasing work rate, phosphorylase transformation to its active phosphorylated form is not (Howlett *et al*., 1998). This suggests that allosteric regulators may be important activators of glycogen phosphorylase during exercise (Rush and Spriet, 2001). $\beta-$adrenergic receptor stimulation by catecholamines play a major role in the mobilization of muscle glycogen during exercise (Wasserman and Cherrington, 1996).

Exercise-induced muscle glucose uptake

Muscle glucose uptake requires glucose delivery from blood to muscle, membrane glucose transport and muscle-glucose phosphorylation. Exercise-induced increase in glucose delivery is so efficient at maintaining interstitial glucose that an increase in muscle fractional glucose extraction is not required for increase in muscle glucose uptake (Hargreaves *et al*., 1991). Exercise also increases glucose transport by stimulating GLUT4 translocation to the muscle cell surface (Lund *et al.,* 1995).

2.7.2.2 Diet

Essentially, eating plan for type 2 diabetic should be tailored at foods that are low in refined grains and sugar, low in saturated and trans fats and high in fiber (Cousens, 2013).

Glycemic index (G1)

Glycemic index is a scale (0-100) ranking how quickly a carbohydrate containing food will digest into glucose in our blood. High G1 foods break down quickly whereas low G1 foods breack down slowly. With low G1 foods, one feels full longer and ones bodyôs insulin has more time to perform its work of removing the glucose from the blood.

Table 7: Different food stuffs and their glycemic indices

	Low G1 foods 55 or less	Medium G1 foods 56-69	High G1 foods 70 & above
1	Whole grain bread	Couscous	White bread
2	Pumpernicle bread	Rye bread	Instant mashed potatoe
3	Oat meal	Instant oat meal	Corn flakes, Rice Krispies
4	All-bran cereal	Shredded wheat	Refined, sweetened cereals
5	Converted rice	Cream of wheat	Instant rice
6	Brown and basmati rice	Whole grain crackers	Bagels
7	Bulgur, Barley, Quinoa	Pita bread	Waffles/pancakes made
8	Firm cooked pasta	Long grain while pice	With white flour
9	Beans, peas, lenfits	Apricot, Bannana	Soda crackers
10	Apples, peaches, peers	Cantaloupe	French fries
11	Grape fruit, oranges	Pinapple, raisins	Dried dates figs
12	Berries, cherries, grapes	Canned fruit in juice	Sweetened fruit jice
13	Kiwi, mango, plum	Cranberry juice	Parsnips, pumpkin
14	Avocado	New potatoes	Rutabaga, turnip
15	Sweet potatoe	Beets	Broad beans
16	Carrots, broccoli	Sweetened conderzes milk	Refried beans
17	Cauliflower corn		Ice cream
18	Leafly vegetables		Soft drink.
19	Low fat milk, soyamilk		Glucose
	Yogurt, & cottage cheese		

Adapted from ñthe GI dietò Rick Gallopò.

www.gidiet.com or www.diabetes.calfiles/glycemicidex-08.pdf. eat more of fibres and drink less alcohol.

2.8 Experimental diabetes

Substances with diabetogenic effect in experimental animals

These include Alloxan, Chlorothiazide, Chlorizotocin, Cyclosporine, Cyproheptadine, Diazoxide, Dithizone, Furosemide Hydrochlorothiazide, L-asparaginase, Methylnitrosourea, Oxime, Streptozotocin, Styrylquinoline, Trichlormethiazides, Vacor, Xylazine (Glenn and Susan, 1981).

Alloxan

Alloxan (2, 4, 5, 6-tetra oxy pyrimidine), is a compound gotten by amalgamation of the word allantein ñand ñoxalsaò. Oxalic acidò, with molecular formular, $C_4 H_2 N_2 O_4$ is a toxic glucose analogue, which selectively destroys insulin-producing cells in the pancreas (beta cells) when administrated to rodents and many other animals. This causes an insulin-dependent *Diabetes mellitus* (called ñalloxan diabetesò) in these animals. (Szukudelski, 2001**).**

Alloxan is selectively toxic to insulin-producing pancreatic beta cells because it preferentially accumulates in beta cells through uptake via the GLUT 2 glucose transporter. Alloxan in the presence of intracellular thiols generates reactive oxygen species (ROS) in a cyclic reaction with its reduction product, dialluric acid. The beta cell toxic action of alloxan is initiated by free radicals formed in this redox reaction (Szkudelskl, 2001).

Alloxan establishes a redox with formation of superoxide to hydrogen peroxide with a simultaneous massive increase in the cytosolic calcium ion concrentration which causes rapid destruction of pancreatic beta cell (Szkudelski, 2001). The range of diabetogenic dose of alloxan is narrow that even slight over dosing may result in the death of animals (Frode and Medeiros, 2008). The most frequently used dose of alloxan is 150 mg/kg given intraperitonealy. The intravenous dose of alloxan is 65 mg/kg (Frode and Medeiros, 2008).

Moreover, the dose of alloxan required for inducing diabetes depends on the animal species, route of administration and nutritional status (Federiuk *et al.,* 2004). Furthermore, alloxan has been demonstrated to be non-toxic to the human beta cells, even in a very high dose. The reason of which may be attributed to the differing glucose uptake mechanism in humans and rodents (Tyrbery *et al*., 2001).

Streptozotocin (STZ)

Streptozotocin is a nitrosurea compound derived from *Streptomyces anchromogenes*, which has also been used as an antibiotic and a cancer treatment. Streptozotocin enters the β cell via a glucose transporter (GLUT2) and causes alkylation of DNA. The DNA damage induces activation of poly ADP-ribosylation, a process that is more important for diabetogenicity of streptozotocin than DNA damage itself. Poly ADP-ribosylation leads to depletion of cellular NAD^+ and ATP. Enhanced ATP dephosphorylation after streptozotocin treatment supplies a substrate for xanthine oxidize resulting in the formation of superoxide radicals consequently, hydrogen peroxide and hydroxyl radicals are also generated. Further more streptozotocin liberates toxic amounts of nitric oxide that inhibits aconitase activity and participates in DNA damage. As a result of the streptozotocin action, β cells undergo the destruction by necrosis (Szkuldeski, 2001).

In adult rats, 60 mg/kg is the most common dose of STZ to induce insulin dependent diabetes, but higher dose are also used. It is also efficacious after intraperitoneal administration of a similar or higher dose but single doses below 40 mg/kg may be effective (Frode and Medeiros, 2008). In mice multiple low doses (40 mg/kg) are the most effective at maintaining mouse viability and inducing pancreatic dysfunction in part through immune destruction (Katherine and Laura, 2009).

Induction of diabetes with streptozocin leads to a spontenous reduction of hyperglycemia by the developments of functioning insulinoma. There is also a high incidence of kidney and liver tumors (Etuk, 2010).

2.9 Chromatography

Chromatography is the general name applied to a series of separation methods that employ a system with two phases of matter, a mobile phase and a stationary phase. Analytes in a mixture to be separated interact with the stationary phase with different affinities while moving through the system, carried along by the mobile phase. The analytes with a low affinity for the stationary phase will tend to move along rapidly while those with high affinity will tend to lag behind. Thus the separation of analytes in chromatographic system is based on the differential affinity of the analyte for the stationary verses mobile phases.

Column chromatography (CC)

Column chromatography consists of a common of particulate material such as silica or alumina that has a solvent passed through it at atmospheric, medium or low pressure. The columns are usually glass with sinter frits to hold the packing. Most systems utilize gravity to push the solvent through but medium pressure pumps are commonly used in flash column chromatography. The sample is dissolved in solvent and applied to the front of the column (wet packing) or alternatively adsorbed on a coarse silica gel (dry packing). The solvent elutes the sample through the column, allowing the component to separate.

The solvent is usually changed stepwise, and fractions are collected according to the separation required, with the eluting products usually monitored by Thin Layer Chromatography. The technique is not efficient, with relatively large volumes of solvent being used and particle size is constrained by the need to have a flow of several ml/min. The advantage is that no

expensive equipment is required and the technique can be scaled up to handle sample sizes approaching gram amounts (Guiochon 2001).

Other forms of chromatography incude: high pressure liquid chromatography, thin layer chromatography, gel permeation chromatography and gas chromatography (GC).

2.10 Spectroscopic techniques

Nuclear magnetic resonance spectroscopy (NMR)

Spectroscopy is the study of the interaction between electromagnetic radiation (EMR) and matter. Nuclear magnetic resonance spectroscopy is the study of interaction of radio frequency (RF) of the EMR with unpaired nuclear spins in an external magnetic field to extract structural information about a given sample. The chemical structures of simple and complex compounds are determined by one dimensional techniques (1D-NMR) and two dimensional techniques (2D-NMR) resspectively (Abraham *et al.,* 1988).

One dimensional NMR ID-Proton NMR (^{1}H-NMR)

Proton NMR is a plot of signals arising from absorption of RF during an NMR experiment by the different protons in a compound under study as a function of frequency (chemical shift). The area under the plots gives information about the number of protons present in the molecule, the position of the signals (the chemical shift) reveals information regarding the chemical and electronic environment of the protons, and the splitting pattern provides information about the number of neighboring (Vicinal or germinal) protons (Sanders and Hunter, 1993).

1D-Carbon NMR (13^{C} NMR)

Carbon NMR is a plot of signals arising from the different carbons as a function of chemical shift. The signals in 13c-NMR experiments usually appear as singlets because of the decoupling of the attached protons. Different techniques of recording of the 1D-Carbon NMR have been

developed so that it is possible to differentiate between the various types of carbons such as the primary, secondary, tertiary and quaternary from the 1D ^{13}C-NMR plot. The range of the chemical shift values differs between the ^{1}H (normally 0-10) and 13C- NMR (Normally 0-230) that arise from the two nucleic having different numbers of electorns around their corresponding nucleic as well as different electronic configurations (Abraham *et al.,* 1988).

Other special forms of spectroscopy include: 2d Nuclear Overhauser Enhancement Spectroscopy (NOESY), Heteronuclear Multiple Bond Correlation (HMBC), Gas Chromatography/Mass Spectrometry (GC/MS), Mass Spectrometry (MS), Liquid Chromatography/ Mass Spectrometry (LC/MS).

2.11 *Cussonia arborea*

2.11.1 Scientific classification of *Cussonia arborea*

Kingdom: Plantae

Unranked: Angiosperms

Unranked: Eudicots

Order: Apiales

Family: Araliaceae

Subfamily: Aralioideae

Genus: Cussonia

Species: arborea

Other species of Cussonia

1. *Cussonia angolensis*

2. *Cussonia arenicola*
3. *Cussonia bancoensis*
4. *Cussonia brieyi*
5. *Cussonia corbisieri*
6. *Cussonia gamtoosensis*
7. *Cussonia holsti*
8. *Cussonia jatrophoides*
9. *Cussonia natalensis*
10. *Cussonia nicholsoni*
11. *Cussonia ostinii*
12. *Cussonia paniculata*
13. *Cussonia sessilis*
14. *Cussonia sphaerocephala*
15. *Cussonia spicata*
16. *Cussonia thyrsiflora*
17. *Cussonia transvaalensis*
18. *Cussonia zimmermannir*
19. *Cussonia zuluensis*

(Adapted from wikipedia **2015)**

Identification of Cussonia arborea

Fig.2 *Cussonia arborea* plant in its natural habitat

Fig.3: The stem of *Cussonia arborea* plant in its natural habitat

2.11.2 **Different local names of the plant**

The different local names of the plant are as follows: Mufenje by Yoruba,
Hannun kuturuu (Lepers Hand), Takandar giiwaa (elephant sugarcane) by Hausa Ityovor by TIV people, Kijagaajaga by Bukoba rural district in Tanzania; no specific local name has been associated with the plant in Igbo land.

2.11.3 Geographical distribution: It is widely distributed across Tropical Africa.

Cussonia arborea (Hochst) is a tree that originated from Africa and has its centre of distribution in South Africa and Madagascar (Tennant, 2010). The tree can grow up to 11m tall with a bole of up to 0.75 diameters; bark deeply fissured and corky. The leaves are digitately compound ; petiole up to 87cm long and 9 mm wide but usually much smaller, mostly glabrous or somewhat hairy in places ; leaflets 5-9, sessile, chartaceous to coriaceous to oblanceolate, ovate and obviate up to 23 cm long by 10.5 cm wide. Flowering spikes up to about 26 together, but mostly less than 12, up to 46 cm long, sometimes galled (Tennant, 2010**).** In the dry season, the tree becomes completely defoliated, and the thick stumpy branches resembling amputated and deformed limbs sticking up into the sky invoke the Bambara name in Mali ñstump of an amputated linbò and in upper Volta ñcut handò and the Hausa name in Northern Nigeria ñLeperôs handò. The wood is dirty white, soft and brittle (Tennant, 2010**).**

Habitat: In Brachystegia woodland, often in rocky terrain

Altitude: 850-1750 M

Flowering time: September to November

2.11.4 Folkloric uses of *Cussonia arborea*

1. Antifungal and for treatment of chronic diarrhea (Kinsangau *et al.*, 2007**)**
2. Antimicrobial and antimalarial effects (De villiers *et al.,* 2010)
3. For the treatment of pain, inflammation and sexually transmitted diseases (De villiers *et al.*, 2010).
4. Hypoglycemic potential (Amadou *et al.*,2008**)**

Despite considerable progress in the treatment of diabetes by oral hypoglycemic agents, search for newer drugs continues because the existing synthetic drugs have several limitations. The herbal drugs with antidiabetic activity are yet to be commercially formulated as modern medicines, even though they have been acclaimed for their therapeutic properties in the traditional systems of medicine (Wadkar *et al.,* 2008**).** The plants provide a potential source of hypoglycemic drugs because many plants and plant derived compounds have been used in the treatment of diabetes. Ayurveda and other traditional medicinal systems for the treatment of diabetes describe a number of plants used as herbal drugs. Hence, they play an important role as alternative medicine due to less side effects and low cost. The active principles present in medicinal plants have been reported to possess pancreatic beta cells re-generating, insulin releasing and fighting the problem of insulin resistance (Welihinda *et al.,* 1982). Hypoglycemic herbs increase insulin secretion, enhance glucose uptake by adipose or muscle tissues and inhibit glucose absorption from the intestine and glucose production from liver (Hongxiang *et al.,* 2009). Insulin and oral hypoglycemic agents like sulphonylureas and biguanides are still the major players in the management but there is quest for the development of more effective anti-diabetic agents.

CHAPTER THREE

MATERIALS AND METHODS

3.1 Materials:

3.1.1 Chemicals and reagents

Chloroform, Methanol, Ethylacetate and Hexane were obtained from Sigma Aldrich, U.K., Test kits (Randox, UK), Glycosylated hemoglobin Kit (Spectrum, Egypt)

Ferric Reducing Antioxidant Power (FRAP) reagents

1, 1 diphenyl-2-picrynyl phenyl hydrazyl (DPPH) reagents

Glucometer strip, RBC, WBC diluting fluids, Drapkins reagent, MDA, SOD, GSH and Catalase reagents

Silica gel (Laboratory Tech. Chemicals)

3.1.2 I**nstruments and glassware**

1. Glucometer (Accu-Chek Advantage II)
2. Gastric gavage
3. Electronic weighing balance (Mettler, England)
4. Beakers, test tubes, graduated cylinder
5. Oven (Gallenkamp, England)
6. Votex machine
7. Spatular, funnel, filter paper, scissors
8. Spectrophotometer (Spectrum Lab. 752s, England)
9. Column glassware (Pyrex)
10. UV lamp (YLN, China)
11. Refrigerator (Haier Thermocool)

12. Water bath (Techmel and Techmel, Texas, USA)
13. Stirrer (glass rod)
14. Thin layer chromatography plate and container (De Saga)
15. Cotton wool
16. Crocodile clip, syringes
17. Mortar and pestle
18. Capillary tubes
19. Rotary evaporator (Buchii, Switzerland)
20. Analytical weighing balance (Scientific and Instrument Company, England)
21. Microhaematocrit Centrifuge
22. Centrifuge
23. Microscope
24. Microscope slides
25. NMR machine
26. 20cm x20cm chromatographic plates, chromatographic tank

Drugs

1. Glibenclamide
2. Alloxan monohydrate

3.1.3 Animals

Male albino Wistar rats weighing between 100 g and 105 g were obtained from the Department of Veterinary Physiology and Pharmacology, University of Nigeria, Nsukka. The rats were acclimatized for two weeks. The environmental temperature where the animals were housed varied between 28 and 32^{0C}. The animals were kept in stainless wire mesh cages and provided

with good clean water *ad libitum*. They were fed with standard commercial feed (Guinea^{R} growers, Benin).

3.1.4 Plant material

The root bark of the plant material (*Cussonia arborea*) used in this study was collected from Orukpa Local Government Area of Benue state and identified by a plant taxonomist, Mr. Ozioko at the International Centre for Ethnomedicine and Drug Development, Echara, Aku Road, Nsukka.

3.2 Methods

3.2.1 Preparation of the plant extract

Cold maceration method of extraction was employed. The root bark of *C. arborea* was air dried at a very low intensity of sunlight to avoid denaturation of the active ingredient. It was pulverized and stored in an air tight container pending its usage. About 2 kg of the powdered stem bark was soaked in 10 liters of 80% methanol with intermittent shaking every 2 h for 48 h. The mixture was filtered using Whatmann No 1 filter paper. The filtrate was concentrated using rotary evaporator and the extract was stored in a refrigerator at 4^{OC}.

Calculation of the percentage yield

$$\textbf{Percentage yield} = \frac{\text{Mass of the extract} \times 100}{\text{Mass of the starting material}}$$

Weight of beaker=Y g

Weight of extract=(X-Y) g

Weight of beaker+ extract=X g

$$\% \text{ of extract yield} = \frac{(X-Y)}{2000g} \times 100$$

3.2.2 Acute toxicity test

Acute toxicity test according to the method of Aba *et al.,* (2014) was used. Rats were divided into seven groups consisting of five rats per group. Groups 1, 2, 3, 4, 5 and 6 were given (orally) graded doses (500 mg/kg, 1000 mg/kg, 2000 mg/kg, 3000 mg/kg, 4000 mg/kg, and 5000 mg/kg) of the extract respectively. The rats in group seven received distilled water (10 ml/kg) to represent the negative control. The rats were watched closely for 48 h for signs of toxicity such as sedation, dullness, anxiety, wretching, anaesthesia and death.

3.2.3 Induction of experimental *Diabetes mellitus*

Diabetes was induced in rats using the method described by Venugopal *et al.,* (1998). The rats were injected with alloxan monohydrate dissolved in distilled water at a dose of 150 mg/kg body weight intraperitoneally, after overnight fasting (18 hours). Meanwhile before the injection with alloxan monohydrate, the blood glucose levels of the rats were taken using Accu-Check glucometer. This was done by tail snip of the rats and allowing blood to drop on the Glucometer strip. The value was digitally read off on the screen of the glucometer. After induction, the rats were kept in clean stainless steel cages and fed with commercial feed and were also given clean water for about 2 days. The rats were fasted overnight before the assessment of their blood glucose status on the 2nd day. The fasting blood glucose values above 7 mMol/L (126 mg/dl) were considered diabetic.

3.2.4: Effect of *Cussonia arborea* extract (CAE) on blood glucose level of alloxan-induced hyperglycaemia/dose response study

Diabetes was induced by the method described by Venugopal *et al*., (1998). However, the fasting blood sugar (FBS) levels of the rats were measured before diabetes induction (pre-induction

fasting blood glucose) (FBG).The diabetic rats were randomly assigned into six groups consisting of six rats per group, their fasting blood glucose measured and regarded as Fasting Blood Glucose (FBG) 0 h and treated as follow:

Group 1: 250 mg/kg CAE (Low dose)

Group 2: 500 mg/kg CAE (Medium dose)

Group 3: 1000 mg/kg CAE (High dose)

Group 4: 2 mg/kg Glibenclamide (Standard control)

Group 5: 10 ml/kg distilled water (negative control)

Group 6: non-diabetic + 10 ml/kg distilled water (Normal control)

The FBG was measured at 1h, 3 h, 6 h and 24 h post drug and extract administration.

3.2.5 Antioxidant test

Ferric Reducing Antioxidant Power (FRAP) and 1, 1 Diphenyl- 2- picryl hydrazyl (DPPH) models for assaying *in vitro* antioxidant properties were adopted.

The method of Benzie and Strain, (**1999)** was used for FRAP test. The procedure was as follows:

A. **FRAP reagent preparation**

1. Exactly 3.1 g of Na-acetate trihydrate was weighed out and added to 16 ml of glacial acetic acid. The volume was made up to a litre with distilled water.
2. Ten millimol of TPTZ (Tripyridyltriazine) in 40 mMol HCL was prepared.
3. Twenty millimol of $FeCl_3.6H_20$ was prepared.

1, 2 and 3 above were mixed in the ratio of 10:1:1 to form a working FRAP reagent.

Sample preparation

Serial dilutions of the samples were made in triplicates. The concentrations of 10 µg/ml, 50 µg/ml, 100 µg/ml, 200 µg/ml and 400 µg/ml of the extracts were made. Ascorbic acid was used as standard. Three milliliter (3 ml) FRAP reagent was used to blank the spectrophotometer while mixture of FRAP reagent and Ascorbic acid served as the standard.

Experimental procedure

One hundred microliter (0.1 ml) of the sample was mixed with 3000 µl (3 ml) of the working FRAP reagent and the mixture was shaken properly. The absorbance was read in a spectrophotometer at 593 nm after mixing. The procedure was done for all concentrations. Thereafter, samples were placed at 37^{o}C in water bath and their absorbencies measured after 4 mins. Ascorbic acid standard was processed in the same way. The antioxidant values of the different concentrations of the sample were calculated using the formular below:

$$\text{FRAP value of sample (µm)} = \frac{\text{Change in the absorbance of sample (0-4 min)}}{\text{Change in absorbance of the standard from (0-4 min)}} \times 100$$

NB: the FRAP value of the standard (Ascorbic acid) = 2 µm

B. **DPPH model of *in vitro* analysis of antioxidant property**

Extract preparation

The method of Mensor *et al.,* (2001) was used. Six serial dilutions of the extract were prepared. The concentrations were: 10, 50, 100, 200 and 400 µg/ml. Extracts and DPPH reagent were mixed in the first triplicates of the different concentrations to serve as the test sample, while the remaining triplicates which served as blank contained the extract and methanol. One milliliter (1ml) of DPPH reagent and 2 ml of methanol served as negative control.

Test procedure

Two milliliter (2 ml) of the extract at different concentrations was mixed with 1 ml of 0.5 mMol DPPH (in methanol) in a curvet. The absorbance at 517nm was read at 0 min and 30th minute following incubation in the dark at room temperature. One ml (1 ml) of methanol plus 2 ml of the extract was used as blank while 0.2 mMol DPPH solution plus 2 ml of methanol was used as the negative control. All the experiments were carried out in triplicate.

Ascorbic acid (Vitamin C) was processed in the same way as the extract, as described earlier. Ascorbic acid was used as reference standard. The antioxidant activities of both the extract and the reference standard (Ascorbic acid) were calculated using the formular below:

$$\% \textbf{ Antioxidant Activity} = 100 - \frac{\{(abs_{Sample} - abs_{Blank}) x 100\}}{\text{Absorbance of the control}}$$

NB: Abs=absorbance

3.2.6 Table 8: Effect of CAE on oral glucose tolerance test (OGTT)

Thirty rats were randomly assigned into 5 groups, their FBG levels were measured and then the rats were treated as follows after 18 h fasting

Group	Treatments	30 mins post treatment
1	250 mg/kg CAE	Glucose (2000 mg/kg)
2	500 mg/kg CAE	Glucose (2000 mg/kg)
3	1000 mg/kg CAE	Glucose (2000 mg/kg)
4	2 mg/kg Glibenclamide	Glucose (2000 mg/kg)
5	10 ml/kg distilled water	Glucose (2000 mg/kg)

FBS checked after 30 min, 60 min, 120 min and 180 min post glucose challenge

3.2.7 Phytochemical test

The method of Trease and Evans (1989) was used to determine the phytochemical constituents of the extract.

A. Test for the presence of tannins

A volume of 3 ml of the extract was placed into 3 test tubes. A few drops of lead subacetate were added into the first test tube while 5 ml of dilute sulphuric acid was added to the second tube. Into the third tube was added a few drops of ferric chloride. Distilled water in another test tube was used as control. Brownish colour in lead acetate and yellow colour appearance in dilute sulphuric acid indicates the presence of tannins. The control showed no colour change. Bluish-black precipitate with ferric chloride shows the presence of tannins while the negative control was yellow in colour

B. Test for the presence of alkaloid

To 1 ml of the extract in three test tubes was added a few drops of Wagner`s reagent in test tube 1, Meyer`s reagent in test tube 2 and Draggendorffôs reagent in test tube 3 and distilled water in another test tube served as the control. Intense yellow colour in Wagners reagent test when the control is light yellow indicates positivity. Slight yellow in Meyer`s reagent test as the control remains colourless also indicates presence of alkaloid. Dirty yellow precipitate in Draggendorff`s reagent test shows positivity as the control has brick-red precipitate.

C. Test for the presence of flavonoids

One milliliter (1 ml) of the extract was diluted to 5 ml with distilled water in a test tube. One milliliter (1 ml) of 20% sodium hydroxide was added and water was used as control. Intense yellow colour would indicate the presence of flavonoids.

D. Test for the presence of glycosides

To 5 ml of the extract in a test tube was added 2 ml of dilute sulphuric acid, heated, cooled and neutralized with equal volume of sodium hydroxide solution. This was boiled. About 5 ml of fehling`s`solutions I and II mixture was added and heated for 5 to 10 mins and cooled. Water

was used as negative control. Brick-red precipitate at the bottom of the test tube shows a positive test for glycoside if there is no such precipitate in the control tube (tube containing H_2SO_4, NaOH, Fehling`s I and II).

E. **Test for the presence of saponins**

I. **Frothing Test**: Three milliliter (3 ml) of the extract was diluted to 10 ml with distilled water. The solution was shaken vigorously for 30 seconds and allowed to stand. If there is much foaming, saponin is present.

II. Emulsifying Test: One drop of olive oil was added to the solution in I above and shaken vigorously. Saponin was used as a positive control while distilled water served as negative control. If emulsification is observed, saponin is present.

Test for Sterols/Terpenes

Ten (10) ml of extract was evaporated to dryness in a beaker. The residue was dissolved in 1 ml acetic acid anhydride and 1 ml chloroform. This was transferred to a dry test tube into which 2 ml of concentrated sulphuric acid was added. Formation of a brownish or violet ring at the zone of contact with supernatant indicated the presence of sterols/terpenes.

3.2.8 Chronic antidiabetic study

Seventy two (72) male albino rats weighing between 100 and 105 g were assigned into six groups of 12 rats per group. Diabetes as described by Venugopal *et al.,* (1998**),** was induced in 60 rats while the remaining 12 rats served as normal control. The rats were treated as follows:

Group 1: Diabetic rats treated with 62.5 mg/kg CAE

Group 2: Diabetic rats treated with 125 mg/kg CAE

Group 3: Diabetic rats treated with 250 mg/kg CAE

Group 4: Diabetic rats treated with 2 mg/kg Glibenclamide

Group 5: Diabetic rats treated with 10 ml/kg Distilled water

Group 6: nondiabetic rats treated with 10 ml/kg Distilled water

The rats were treated daily for eighty four (84) days. The biochemical [(Aspartate aminotransferase (AST), Alanine aminotransferase (ALT), Total Cholesterol, Triglyceride, High Density Lipoprotein (HDL), Very Low Density Lipoprotein (VLDL), Low Density Lipoprotein (LDL), Total Protein, Albumin, Globulin, Blood Urea Nitrogen, Creatinine, Total Bilirubin, Conjugated Bilirubin, Unconjugated Bilirubin, Malondialdehyde (MDA), Superoxide Dismutase (SOD), Catalase, and Reduced Glutathione) and haematologic (Red Blood Cell (RBC), Haemoglobin (HB), Packed Cell Volume (PCV), White Blood Cell (WBC), differential leucocytes (Lymphocytes, Neutrophils, Basophils, Eosinophils and Monocytes), Mean Corpuscular Volume (MCV), Mean Corpuscular Haemoglobin (MCH), Mean Corpuscular Haemoglobin Concentration (MCHC))] parameters were assayed on days 28, 56 and 84 while the Glycosylated Haemoglobin (HbA_{1c}) was measured on days 42, 56 and 84. Three rats per group, upon collection of blood samples, were also sacrificed on days 28, 56 and 84 for histomorphologic assessment. The Fasting Blood Glucose (FBG) levels and the weights of the rats were taken after every 2 weeks till the duration of the experiment. Blood samples for haematology were obtained through the medial canthus of the ratsô eyes into an EDTA bottle while the blood for serology was allowed to clot, centrifuged and serum decanted into a clean bijou bottle.

3.2.9 Glycosylated haemoglobin

This was done by ion-exchange resin method (English *et al*., 2014) using Glycosylated hemoglobin Kit (Spectrum, Egypt)

Assay principle

A hemolysed preparation of whole blood was mixed continuously for 5 mins with a weakly binding cation- exchange resin. The labile fraction was eliminated during the hemolysate preparation and during the binding. During this mixing, HBA_0 binds to the ion-exchange resin leaving GHb free in the supernatant. After the mixing period, a filter separator was used to remove the resin from the supernatant. The percent GHb was determined by measuring the ratio of the absorbances of the glycosylated haemoglobin (GHb) and the total haemoglobin fraction (THb). The ratio of the absorbances of GHb and THb of the control and test was used to calculate the percent GHb of the sample.

Procedure

A. Hemolysate preparation

Into a test tube was dispensed 0.5 ml of lysing reagent and labeled as test and control. Thereafter, 0.1 ml of the reconstituted control or well mixed sample was added into the appropriately labeled tubes and mixed until complete lysis was evident.

B. Glycosylated haemoglobin separation

The cap from the ion exchange resin was removed and labeled as control and test and 0.1ml of hemolysate from step A above was added into appropriately labeled ion exchange resin tubes. Thereafter, a resin separator was inserted into each tube so that the rubber sleeve was approximately 1cm above the liquid level of the resin suspension and the tube was vortexed continuously for 5 mins. The resin was allowed to settle and the resin separator was pushed until the resin was firmly packed and the supernatant decanted directly into a curvette and absorbance measured at 415 nm against distilled water.

C. Total haemoglobin fraction

In to a test tube labeled as test and control was dispensed 5 ml of distilled water and 0.02 ml of hemolysate from step A above added to appropriately labeled tube. The mixture was mixed well and the absorbance read against distilled water.

Calculations

Ratio of Control (R_c)= Absorbance control GHb / Absorbance control THb

Ratio of test (R_t)= Absorbance test GHb / Absorbance test THb

GHb (%) = Ratio of Test (R_t) / Ratio of control (R_c) X 10

10 is the value of the control.

3.2.10 Determinations of serum biochemistry parameters

3.2.10.1 Assay of aspartate aminotransferase activity

The method of Reitman and Frankel (1957) using Randox Commercial Enzyme kit was used.

This method is based on the principle that oxaloacetate is formed from the reaction below:

αï Oxoglutarate + L ï aspartate ⟶ L-glutamate + oxaloacetate

Glutamic-oxaloacetic acid transaminase (aspartate aminotransferase) activity was measured by monitoring the concentration of oxaloacetate hydrazone formed with 2,4-dinitrophenyl hydrazine.

Reagents

	Contents	Initial concentration of reagents
1.	Buffer	
	Phosphate buffer	100 mmol/l, pH 7.4
	Lï Aspartate	100 mmol/l
	αï Oxoglutarate	2 mmol/l
2.	2, 4ï dinitrophenyl hydrazine	2 mmol/l
	Sodium hydroxide solution	0.4mol/l

1. Measurement against reagent blank

The AST substrate phosphate buffer (0.5ml each) was pipetted into both the reagent blank (B) and sample (T) test tubes respectively. The serum sample (0.6ml) was added to the sample (T) test tubes only and mixed thoroughly. Then 0.1ml of distilled water was added to the reagent blank (B). The entire reaction medium was well mixed and incubated for 30 min in a water bath at 37^{o}C.

Immediately after incubation, 2, 4-dinitrophenyl-hydrazine (0.5ml) was added to the reagent blank (B) and the sample (T) test tubes, mixed thoroughly and allowed to stand for exactly 20 min at 25^{o}C. Finally, 5.0 ml of sodium hydroxide (0.4 mol/l) solution was added to both the blank and the reagent test tubes respectively and mixed thoroughly.

The absorbance of sample was read at a wavelength of 550 nm against the reagent blank after 5 min.

2. Measurement against sample blank

The AST substrate phosphate buffer (0.5ml each) was pipetted into the sample blank (B) and sample (T) test tubes respectively. The serum sample (0.1ml) was added to the sample test (T) only and mixed immediately then incubated in a water bath for exactly 30 min at 37^{o}C.

2, 4 ï Dinitrophenylhyrazine was added to both sample blank (B) and sample (T) test tubes immediately after incubation. Also, 0.1ml of the sample was added to the sample blank (B) only. Each medium was mixed and allowed to stand for exactly 20 min at 25^{o}C. Finally, 5.0ml of sodium hydroxide (NaOH) solution 0.4 mol/l was added to both the sample blank (B) and sample (T) test tubes and mixed thoroughly. Absorbance of the sample was read with spectrophotometer at a wavelength of 550 nm against the sample blank after 5min.

3.2.10.2 Assay of alanine aminotransferase activity

The method of Reitman and Frankel (1957) using Randox Commercial Enzyme kit was used.

Alanine aminotransferase assay is based on the principle that pyruvate is formed from:

αï Oxoglutarate + L-alanine ⟶ L-glutamate + pyruvate

Alanine aminotransferase is measured by monitoring the concentration of pyruvate hydrazine formed with 2, 4ï dinitrophenyl hydrazine.

Reagents

Contents	**Initial concentrations of solutions**
Buffer	
Phosphate buffer	100 mmol/l pH 7.4
Lï alanine	200 mmol/l
αï oxoglutarate	2.0 mmol/l
2, 4ï dinitrophenyl hydrazine	2.0 mmol/l
Sodium hydroxide solution	0.4 mol/l

Procedure

Measurement against sample blank

The ALT substrate phosphate buffer (0.5ml each) was pipetted into two sets of test tubes labeled B (sample blank) and T (sample test respectively). The serum (0.1ml) sample was added to the sample test (T) only and mixed properly, then incubated for exactly 30 min in a water bath at a temperature of 37^{o}C.

2, 4ï dinitrophenyl hydrazine (0.5 ml) was added to both test tubes labeled T (sample test) and B (sample blank) immediately after the incubation. Also, 0.1ml of serum sample was added to the sample blank (B) only. The entire medium was mixed thoroughly and allowed to stand for exactly 20 min at 25^{o}C. After which, 5.0 ml of sodium hydroxide (NaOH) solution (0.4 mol/l) was added to both test tubes and also mixed thoroughly. Absorbance of the sample was read at a wavelength of 546 nm after 5min.

Measurement against reagent blank

The ALT substrate phosphate buffer (0.5ml each) was pipetted into both the reagent blank (B) and sample (T) test tubes respectively. The serum sample 0.1ml was added to the sample (T) test tube only and mixed thoroughly. Then 0.1ml of distilled water was added to the reagent blank (B). The entire medium was mixed and incubated for exactly 30 min in a water bath at 37^{o}C. Immediately after incubation, 2,4 ï dinitrophenylï hydrazine (0.5ml) was added to both reagent blank and sample (T) test tubes. The contents of the tubes were mixed thoroughly and allowed to stand for exactly 20 min at 25^{o}C. Finally, 5.0 ml of sodium hydroxide solution (0.4 mol/l) was added to both the blank and reagent test tubes respectively. Each was mixed thoroughly and absorbance of sample was read at a wavelength of 546 nm against the reagent blank after 5min using spectrophotometer.

AST: ALT ratio

This was determined by dividing the AST value with corresponding ALT value (Reitman and Frankel, 1957).

3.2.10.3 Determination of total proteins

Total proteins were determined by the direct Biuret method (Tietz, 1995), for the in-vitro determination of total proteins in serum or plasma using the total proteins test kit (Randox, UK). The serum sample (0.02 ml) was mixed and reacted with Cu^{2+} contained in 1 ml of diluted Biuret reagent in a clean test tube, to form a stable coloured complex. The mixture was allowed to stand for 30 mins at room temperature. A standard was prepared by adding 1ml of the Biuret reagent and 0.02 ml of the standard into a clean test tube. This was mixed properly and allowed to stand for 30 mins. After this, the absorbances of both the sample and standard were read at 546 nm against the working reagent blank using a spectrophotometer.

The total proteins concentration was obtained with the formula:

$$\frac{\text{Absorbance of sample}}{\text{Absorbance of standard}} \times 5.95 = \text{Total protein (g/dl)}$$

3.2.10.4 Determination of serum albumin

The serum albumin was determined by the bromocresol green method (Doumas *et al*. 1971**),** for the *in vitro* determination of albumin in serum or plasma using albumin test kit (Randox, UK). The serum sample (0.01 ml) was mixed properly in 3.0 ml of diluted bromocresol green reagent for 5 minutes in a clean test tube to produce a coloured complex. The standard was also prepared by adding 3.0 ml of bromocresol reagent and 0.01 ml of standard. The absorbances of both the sample and standard were read immediately after reaction for 5 minutes at 630 nm against the

working reagent blank, using a Spectrophotometer. The concentration of albumin was obtained using the formula below:

$$\frac{\text{Absorbance of sample}}{\text{Absorbance of standard}} \times 4.66 = \text{Albumin (g/dl)}$$

3.2.10.5 Determination of serum globulin

The serum globulin was obtained by the subtracting the serum albumin value from the total protein value (Colville, 2002). The concentration of serum globulin was obtained using the formular below:

Serum total protein (g/dl) ï Serum albumin (g/dl) = Serum globulin (g/dl)

3.2.10.6 Determination of serum cholesterol

The serum cholesterol was determined by cholesterol oxidase-perioxidase method (Allain *et al*., 1974**),** for the *in-vitro* determination of cholesterol in serum or plasma using cholesterol test kit (Randox, UK). The serum sample (0.01 ml) was reacted with 1.0 ml of cholesterol working reagent containing cholesterol esterase, oxidase and peroxidase to form a colored quinolic derivative. It was mixed properly and allowed to stand at room temperature for 10 mins. The standard was also prepared by adding 1.0 ml of cholesterol working reagent and 0.01 ml of standard. It was mixed properly and allowed to stand at room temperature for 10 minutes. The absorbance of both the sample and standard were read against the working reagent blank at 500 nm within 60 mins with a digital spectrophotometer. The cholesterol concentration in each sample was obtained with the formula:

$$\frac{\text{Absorbance of sample}}{\text{Absorbance of standard}} \times 206 = \text{Cholesterol concentration (mg/dl)}$$

3.2.10.7 HDL-Cholesterol

Principle

Low density lipoproteins (LDL) very low density lipoproteins (VLDL) and chylomicrons fractions are precipitated quantitatively by the addition of phosphotungstic acid in the prescence of magnesium ions. After centrifugation, the cholesterol concentration in the HDL fraction which remains in the supernatant was determined.

Procedure

Precipitation

Five hundred microlitre (500µL) of diluted R1 (phosphotungstic acid and magnesium chloride) was mixed with 200 µL of serum sample or standard and allowed to sit for 10 min at room temperature. Thereafter, the clear supernatant was separated off within 2 h and the cholesterol content was determined by the CHOP-PAP method (Allain *et al*., 1974).

Determination of cholesterol using the supernatant

One hundred micro liter (100 µL) of supernatant (or standard or distilled water for blank as the case may be) was mixed with 1000 µL of reagent, mixed and incubated for 10 min at room temperature.

Absorbances of the sample (Asample) and standard (Astandard) were measured against the reagent blank within 60 mins.

Calculation

$$\textbf{HDL -Cholesterol (mg/dl)} = \frac{\text{change Asample}}{\text{Change Astandard}} \times \text{concentration of standard}$$

LDL-Cholesterol (mg/dl) = Total cholesterol-(Triglyceride/5)-HDL-Cholesterol (Friedwald, 1972**)**

VLDL-Cholesterol (mg/dl) = Triglyceride/5

3.2.10.8 Triglyceride

This was done according to Allain *et al*., (1974**).**

Triglyceride measurement are used in the diagnosis and treatment of diseases involving lipid metabolism and various endocrine disorders such as diabetes mellitus.

R1a= buffer

R1b=Enzyme Reagent

R1b was reconstituted with 15 ml of R1a

Procedure

The serum sample or standard (10 µL) was mixed with 1000 µL of R1, and incubated for 10 mins at room temperature.

The absorbance of the sample (Asample) and standard (Astandard) were read against the blank (1000 µL of R1) at wavelength 500 nm

$$\text{Triglyceride conc. (mg/dl)} = \frac{\text{Asample}}{\text{Astandard}} \times \text{standard concentration}$$

Concentration of standard =191 mg/dl

3.2.10.9 Bilirubin

Both total and conjugated bilirubin were assayed according to Doumas *et al*. (1971**);** direct bilirubin (conjugated) reacts with diazotized sulphanilic acid in alkaline medium to form a blue coloured complex. Total bilirubin is determined in the prescence of caffeine, which releases albumin bound to bilirubin by the reaction with diazotized sulphanilic acid.

Procedure

Sample blank: The serum sample (0.2 ml) was added to 0.2 ml of R1 (sulphanilic acid) and 1ml of R3 (caffeine), mixed and incubated for 10 min at room temperature. Thereafter, R4 (Tartrate) was added and incubated for further 5-30 min.

Sample: To 0.2 ml of serum sample was added 0.2ml of R1, 1 drop (50 µL) of R2 (Nitrite) and 1000 µL of R3 , mixed and incubated for 10 min at room temperature. Thereafter, 1000uL of R4 was added to the mixture and incubated for further 5-30 min.

The absorbance of sample A_{TB} was read against sample blank at wavelength 578 nm.

Calculation

Total Bilirubin (mg/dl) = 10.8x A_{TB}

Direct bilirubin assay

Sample blank: To 0.2 ml of serum sample was added 0.2 ml of R1, 2 ml of 0.9 percent of NaCl and incubated for 10 min at room temperature.

Sample: To 0.2 ml of serum sample was added 0.2 ml of R1, 2 ml of 0.9 % of NaCl , 1 drop (50 µL) of R2 and incubated for 10 min at room temperature.

The absorbance of sample A_{DB} was read against sample blank at wavelength 546 nm.

Calculation

Direct bilirubin (mg/dl)=14.4x A_{DB}

Unconjugated bilirubin = Total bilirubin - conjugated bilirubin (TB - CB)

3.2.10.10 Creatinine

The assay was according to Blass *et al*., (1974). Creatinine is derived from creatinine phosphate in muscle tissues and may be defined as nitrogenous waste product. It is produced and excreted at a constant rate which is proportional to the muscle mass. Creatinine is measured primarily to assess the kidney function and has certain advantage over the measurement of urea. The plasma

level of creatinine is relatively independent of protein ingestion, water intake, rate of urine excretion and exercise thus it has advantage over urea measurement in the assessment of kidney function. It is regarded as the most useful endogenous marker in the diagnosis and treatment of kidney disease. Elevation of plasma creatinine is indicative of under-excretion, suggesting kidney impairment. Reduced levels of plasma creatinine are rare and not clinically significant.

Principle

Creatinine in alkaline solution reacts with picric acid to form a coloured complex. This complex is directly proportional to the amount of creatinine.

Procedure

Working reagent was prepared by mixing equal volume of R1a (Picric acid) and R1b (sodium hydroxide).

The serum sample (0.1 ml) or standard solution (0.1ml) was mixed with 1 ml of working reagent and after 30 sec the absorbance A1 of the standard or sample was obtained. Exactly 2 mins, the absorbance A2 of the standard or sample was also read against air at 492 nm

Calculation

A2-A1 = change in Asample or change in Astandard

$$\text{Conc. Creatinine} = \frac{\text{change in Asample}}{\text{Change in Astandard}} \times \text{conc. of standard}$$

Concentration of standard= 2.08 mg/dl

3.2.10.11 Urea

Urease-berthelot Method (Fawcett and Scott, 1960) was used in determining serum urea concentration.

Principle

Urea in serum is hydrolysed to ammonia in the prescence of urease.

Preparation of reagent

R1a=Urease

R1b=sodium nitropruside

R2=phenol concentrate

R3=hypochlorite concentrate

The contents of R1a was transferred into bottle R1b and mixed gently to form R1. The R2 was diluted with 660 ml of distilled water while R3 was diluted with 750 ml of distilled water.

Procedure

The serum sample or standard or distilled water (10 µL) was mixed with 100 µL of R1, and incubated at 37^0C for 10 mins. Thereafter, 2.5 ml of R2 was added to either the tube containing the sample or standard or blank (distilled water). To the mixture above was also added 2.5 ml of R3, mixed immediately and incubated for 15 mins at 37^0C. The absorbance of the sample (Asample) and standard (Astandard) were read against the blank at the wavelength 546 nm.

Calculation

$$\text{Urea concentration (mg/dl)} = \frac{\text{Asample}}{\text{Astandard}} \times \text{standard concentration}$$

Concentration of the standard= 79.33 mg/dl

3.2.11 Determination of haematological parameters

3.2.11.1 Determination of packed cell volume

The packed cell volume (PCV) was determined by the microhaematocrit method (Thrall and Weiser, 2002). Micro-capillary tubes were almost filled with the anti-coagulated blood samples and one end sealed with plasticine. The filled tubes were centrifuged at 10,000 rpm for 5 min

using a microhaematocrit centrifuge. The PCV was read as a percentage on the microhaematocrit reader (Thrall and Weiser, 2002**).**

3.2.11.2 Determination of haemoglobin concentration

The haemoglobin concentration (Hb) was determined by the cyanmethaemoglobin method (Higgins *et al*. 2008). The blood sample (0.02 ml) was added to 5 ml of Drabkins reagent in a clean test tube. This was mixed gently and kept at room temperature for 20 min to react. The absorbances of both sample and standard were read against a working reagent blank at the wavelength of 540 nm using a spectrophotometer (Lab-tech, India). The haemoglobin concentration of the blood sample was obtained by multiplying the absorbance of the sample with the factor derived from the absorbance and concentration of the standard.

3.2.11.3 Erythrocyte count

The erythrocyte count was determined by the haemocytometer method (Thrall and Weiser, **2002**). Blood sample (0.02 ml) was added to 4 ml of red blood cell diluting fluid (sodium citrate, formaldehyde solution and distilled water) in a clean test tube, to make a 1:200 dilution. A drop of the diluted blood was discharged onto the Neubaeur counting chamber and allowed to settle for 2-3 min. The light dry objective (x 40) of the light microscope was used in carrying out the erythrocyte count, in the five groups of 16 small squares. The number of erythrocytes enumerated for each sample was multiplied by 10,000 to obtain the erythrocyte count per microlitre of blood (Thrall and Weiser, 2002).

3.2.11.4 Total leukocyte count

The total leukocyte count was determined by the haemocytometer method (Thrall and Weiser, **2002**). Blood sample (0.02 ml) of blood was added to 0.38 ml of white blood cell diluting fluid

(glacial acetic acid tinged with gentian violet) in a clean test tube, to make a 1:20 dilution. A drop of the diluted blood was charged onto the Neubaeur chamber and allowed to settle for 2 min. The x10 objective lens of the light microscope was used in making a total count of white blood cells on the four corner squares. The number of cells counted for each blood sample was multiplied by 50 to obtain the total leukocyte count per microlitre of blood (Thrall and Weiser, 2002).

3.2.11.5 Differential leukocyte count

Smears for differential leukocyte counts were prepared on clean slides and stained by the Leishman technique (Thrall and Weiser, 2002). The differential leukocyte count was enumerated by the battlement counting method (Coles, 1986**)**. The x100 (oil immersion) objective lens of the light microscope was used in making a differential leukocyte count and the different cells of the leukocytic series were identified and scored using the differential cell counter (Thrall and Weiser, 2002**).**

3.2.11.6 Determination of mean corpuscular values

The mean corpuscular values ï Mean Corpuscular Volume (MCV), Mean Corpuscular Haemoglobin (MCH), and Mean Corpuscular Haemoglobin Concentration (MCHC) were calculated using standard formulae (Coles, 1986).

3.2.12 *In vivo* antioxidant assay

3.2.12.1 Estimation of Superoxide dismutase

Superoxide dismutase activity was assayed by the method of Kakkar *et al*. (1984). The assay is based on the inhibition of the formation of NADH- phenazine methosulphate-nitroblue tetrazolium formazan. The reaction is initiated by the addition of NADH. After incubation for 90

s, the reaction is stopped by adding glacial acetic acid. The colour developed at the end of the reaction is extracted into n-butanol layer and measured at 520 nm in a spectrophotometer.

The chemicals used were as follows:

1. Sodium pyrophosphate buffer, 0.052 M, pH 8.3
2. Absolute ethanol
3. Chloroform
4. n-Butanol
5. Phenazine methosulphate (PMS), 186 μmol
6. Nitroblue tetrazolium (NBT), 300 μmol
7. Reduced NADH, 780 μmol

Procedure

Plasma (0.5 ml) was diluted to 1.0 ml with ice cold water, followed by 2.5 ml ethanol and 1.5 ml chloroform (chilled reagent). The mixture was shaken for 60 seconds at $4^{o}C$ and then centrifuged. The enzyme activity in the supernatant was determined as follows. The assay mixture contained 1.2 ml of sodium pyrophosphate buffer, 0.1 ml of PMS and 0.3 ml of NBT and approximately diluted enzyme preparation in a total volume of 3 ml. The reaction was started by the addition of 0.2 ml NADH. After incubation at $30^{o}C$ for 90 S, the reaction was stopped by the addition of 1 ml glacial acetic acid. The reaction mixture was stirred vigorously and shaken with 4 ml n-butanol. The mixture was allowed to stand for 10 minutes, centrifuged and butanol layer was separated. The colour intensity of the chromogen in the butanol layer was measured in a spectrophotometer at 520 nm. A system devoid of enzyme served as control. One unit of enzyme activity is defined as the enzyme concentration, which gives 50% inhibition of

NBT reduction in one minute under assay conditions. SOD activity was expressed as U/ml of plasma.

3.2.12.2 Estimation of Catalase

The activity of catalase was assayed by the method of Sinha (1972). Dichromate in acetic acid was reduced to chromic acetate, when heated in the presence of hydrogen peroxide with the formation of per chromic acid as an unstable intermediate. The chromic acetate formed was measured at 590 nm. Catalase was allowed to split H_2O_2 for different periods of time. The reaction was stopped at different time intervals by the addition of dichromate acetic acid mixture and the remaining H_2O_2 was determined by measuring chromic acetate spectrophotometrically after heating the reaction mixture. The chemicals used were as follows:

1. Phosphate buffer, 0.01 M, pH 7
2. Hydrogen peroxide, 0.2 M
3. Potassium dichromate, 5%
4. Dichromate acetic acid reagent: Potassium dichromate and glacial acetic acid were mixed in the ratio 1:3. From this 1 ml was diluted again with 4 ml of acetic acid.
5. Standard hydrogen peroxide, 0.2 mM

Procedure

To 0.9 ml of phosphate, 0.1 ml of plasma and 0.4 ml of H_2O_2 were added. The reaction was after 15, 30, 45 and 60 seconds by adding 2 ml of dichromate acetic acid mixture. The tubes were kept in a boiling water bath for 10 min and cooled. The colour developed was read at 530 nm. Standards in the concentration range of 20-100 µmoles was processed for the test. The activity of catalase was expressed as U/ml for plasma (U- µmoles of H_2O_2 Utilised / second).

$$\text{Catalase activity} = \frac{\log A/B \times 023}{0.00693}$$

3.2.12.3 Reduced glutathione

The reduced glutathione level was determined by the method of Beutler *et al.,* (1963).This method was based on the development of yellow colour when 5,5ô- dithio-bis-2-nitrobenzoic (DTNB) is added to a compound containing sulphydryl groups. The colour developed was read at 412 nm in a spectrophotometer.

The chemicals used were as follows:

1. 0.3 M Disodium hydrogen phosphate

2. 0.1% disodium salt of EDTA

3. Precipitating reagent: 1.67 g of metaphosphoric acid, 0.2 gm of EDTA disodium salt, 30 gm sodium chloride in 1 litre of distilled water.

4. 5,5ô- dithio-bis-2-nitrobenzoic (DTNB) reagent: 40 mg of DTNB in 100 ml of 1% sodium citrate.

5. Standard solution: 10 mg of reduced glutathione in 100 ml distilled water.

Procedure

0.2 ml of sample was mixed with 1.8 ml of EDTA solution. To this 3.0 ml of precipitating reagent was added, mixed thoroughly and kept for 5 minutes before centrifugation. To 2 ml of the filterate, 4 ml of 0.3 M disodium hydrogen phosphate solution and 1 ml of DTNB reagent were added and the colour developed was read at 412 nm in a spectrophotometer. A set of standard solutions containing 20-100 ε g of reduced glutathione was treated similarly. The values were expressed as mg/dl for plasma. The enzyme activities were gotten by dividing the absorbances with the slope of a standard curve (0.009).

3.2.12.4 Estimation of lipid peroxidation (Malondialdehyde)

Lipid peroxidation was estimated by measuring spectrophotometrically the level of the lipid peroxidation product, malondialdehyde (MDA) as described by Wallin *et al.* (1993).

Lipid degradation occurs forming such products as malondialdehyde (from fatty acids with three or more double bonds), ethane and pentane (from the n-terminal carbons of 3 and 6 fatty acids, respectively). MDA reacts with thiobarbituric acid to form a red or pink coloured complex which in acid solution absorbs maximally at 532 nm.

A volume, 0.1 ml of the serum was mixed with 0.9 ml of H_2O in a test tube. A volume, 0.5 ml of 25% TCA (trichloroacetic acid) and 0.5 ml of 1% TBA (thiobarbituric acid) in 0.3% NaOH were also added to the mixture. The mixture was boiled for 40 min in a water-bath and then cooled in cold water. Then 0.1ml of 20% sodium dodecyl sulfate (SDS) was added to the cooled solution and mixed properly. The absorbance was taken at 532 nm and 600 nm against a blank.

$$\% \text{ TBARS} = \frac{A_{532} - A_{600} \times 100}{0.5271 \times 0.1} \quad \text{(mg/dl)}$$

3.2.13 Histopathology examination

The histological examination of the tissues of the pancreas of Wistar male albino rats was done using the method of Drury *et al.* (1967).

A. Fixation and washing

Formalin (10%) was used as the fixative and for the purpose of preservation. A thin section of the tissue (about 1 to 2 cm in diameter) was trimmed with a sharp razor blade. The small pieces of the tissue were placed in the 10% formalin, the container was shaken gently several times to make sure that the fluid had reached all surfaces and that pieces were not sticking to the bottom. This was then incubated at 25^0C for 24 h, to allow proper fixing. The fixed tissue pieces were washed with running water for 24 h to free them from excess fixatives.

B. Dehydration

Water was removed from the tissue before embedding the tissue in paraffin. The dehydration was achieved by immersing the thin sections of the tissue in automatic tissue processor containing 12 jars.The first three (3) jars contained 70, 90 and 95% absolute alcohol respectively. This was done to remove the water content in the tissues. The absolute alcohol reduced the shrinking that occurred in the tissue. The time for each step was 30 min. A second change of absolute alcohol was included to ensure complete removal of water. This was achieved in the second three (3) jars of the automatic tissue processor.

C. Clearing

Solutions of xylene were used for clearing the tissue sections. This step was achieved in the third three (3) jars of the automatic tissue processor. Because the alcohol (ethanol) used for dehydration would not dissolve or mix with molten paraffin, the tissue was immersed in xylene solution which was miscible with both alcohol and paraffin before infiltration could take place.

Clearing was done to remove opacity from dehydrated tissue. A period of 15 min was allowed to elapse before the tissue was removed from the solution for infiltration with paraffin.

D. Infiltration with paraffin

Paraffin wax at 50 to 52°C was used to infiltrate the tissue. The tissue was transferred directly from the clearer to a bath containing melted paraffin. After 30 - 60 min incubation in the first bath, the tissue was then removed to a fresh dish of paraffin contained in the fourth three jars of the automatic tissue processor for a similar length of time.

E. Embedding (Blocking) with Paraffin

As soon as the tissue was thoroughly infiltrated with paraffin, it (paraffin) was allowed to solidify around and within the tissue.

F. Paraffin Sectioning

The embedded blocks were trimmed into squares and fixed in the microtome for sectioning after which the sections were floated on a water bath.

G. Mounting

Glass slides were thoroughly cleaned and a thin smear of albumen fixative was made on the slides. The albumenized slide was used to collect the required section from the rest of the ribbon in the water. The section on the glass slide was kept moist before staining.

H. Staining with haematoxylin

The slides were passed through a series of jars containing alcohols of decreasing strength and various staining solutions.

I. Microscopic observation of slide

The slides prepared were mounted on a photomicroscope, and viewed at different magnifications. The photograph of each of the slides was taken.

3.2.14 Bioassay-guided fractionation/isolation of the active compound (s)

3.2.14.1 Column chromatography

Column chromatography was used to separate the different phytochemical components of the plant extracts. The method of Ergon (1967) was used. The method is as follows.

Packing of the (silica gel) column

1. A piece of wire was used to add a plug of glass wool to the bottom of a glass column. Adequate wool was added but not so much as to prevent the dripping of the eluent.
2. The column was clamped to a retort stand. The clamp was cushioned with soft material to avoid breaking the column.

3. A pinch clamp was placed on the rubber tubing to avoid the escape of the initial eluent (Hexane) as the column was one-third filled with the initial eluent.
4. A slurry of the silica gel in initial eluent was made by pouring silica gel into a beaker of eluent in the ratio of 1:2
5. The slurry was constantly being stirred and quickly but carefully poured into the column to maximize the amount of silica that goes into the column.
6. The pinch clamp was removed to allow the eluent drip into the beaker used in making the slurry in order to rinse it and pour back into the column.
7. Rubber stand was used to tap the side of the column to ensure tight packing of the silica gel. Pasteur pipette was used to rinse the side of the column.
8. The eluent was then drained until none remains above the silica gel before the extract (mixed with powdered silica gel in the ratio of 1:8) was poured on the already packed silica gel.
9. Five hundred milliliter of the initial eluent (Hexane) was then carefully poured on the sample by running it on the side of the column to avoid distorting the sample and consequent formation of air bubble.
10. The pinch camp was removed to allow the eluent to drip as it separates the components.
11. Step 9 was repeated continuously but with different proportion of the eluents mixed in various ratios to make up 500 ml. The eluents used as the column progressed include chloroform, ethylacetate, and methanol (Table 2). Two eluents were mixed to make 500 ml in different proportions at a time.

Table 9: The mixture proportions of the chemicals used for column chromatography

The mixture proportions of the chemicals are summarized in the table below:

	Hexane	Chloroform	Ethylacetate	Methanol
1	100	-	-	**-**
2	80	20	-	**-**
3	60	40	-	**-**
4	40	60	-	**-**
5	20	80	-	**-**
6	-	100	-	**-**
7	-	80	20	**-**
8	-	60	40	**-**
9	-	40	60	**-**
10	-	20	80	**-**
11	-	-	100	**-**
12	-	-	80	20
13	-	-	60	40
14	-	-	40	60
15	-	-	20	80
16	**-**	**-**	**-**	100

12. The fractions were collected as different colours as the column progressed.

These fractions were then analyzed by thin layer chromatography to ascertain if the fractions collected in a container were the same.

3.2.14.2 Thin layer chromatography

This was done to analyze the purity of the compounds and fractions following column chromatography. The method of Ergon (1967) was used. .Compounds that have the same chromatographic band pattern were pooled together, the process is as follows:

1. The fractions from column chromatography were allowed to concentrate to a reasonable extent before spotting on a TLC plate.

2. The eluents/solvents (moving phase) were prepared by mixing chloroform, ethylacetate and methanol in the ratio of 3:2:1 and about 20 ml of the mixture was poured into an air-tight container.
3. A whatman No 1 filter paper was cut and put into the solvent in order to saturate the system before placement of TLC plate.
4. TLC plate was cut and pencil was used to draw a line on which the fractions were spotted using capillary tube.
5. The capillary tip was dipped into the fractions and carefully, a spot was made on the line drawn on the TLC plate. Spotting was done repeatedly to ensure success.
6. Upon saturation of the system, the filter paper was removed and replaced with TLC paper. The container was then tightly closed to allow the solvent system elute the compounds.
7. After about 10 mins, the TLC plate was removed and allowed to dry before viewing under UV light at the frequency of 254 nm and 365 nm.
8. The fractions that show the same band pattern under UV light were pooled together and concentrated in the oven at 37^{o}C.

3.2.14.3 Bioassay-guided screening of the fractions

The fractions (7) gotten after chromatography were subjected to screening to ascertain the particular fraction that has the antidiabetic properties.

Diabetes was induced in groups 1-9 rats as described before by the method of Venugopal *et al.*, (1998). The pre-extract administration blood glucose level was determined. The rats were assigned to 10 groups consisting of 3 rats each. Groups 1-7 received the same dose (12.5 mg/kg) of different fractions of CAE, group 8 rats received 2 mg/kg glibenclamie (standard control)

while rats in groups 9 and 10 received the vehicle (10 ml/kg distilled water) to serve as negative and normal controls respectively.

Following the administration of the fractions, blood was collected from the rats by tip tail cut after 1 hour, 3 hours and 6 hours post extract administration for blood glucose analysis. The fraction which was able to reduce significantly, the blood-glucose level was taken as the fraction that has the anti-hyperglycemic property.

3.2.14.4 Preparative thin layer chromatography (bioassay-guided purification of active fraction)

The active fraction obtained from section 3.2.14.4 was subjected to preparative thin layer chromatography for further purification as follows:

Preparation of preparative TLC plate

This was done using the method of Ergon (1969). Thirty five (35 g) gramme of silica gel (60G) was mixed with 85 ml of distilled water in a ceramic motar to form a slurry. The slurry was poured into a trough of movable spreader adjusted to 0.5 mm thickness. The slurry was spread on 5 glass plates measuring 20x20 cm placed in a rack. Thereafter, the plates were air dried.

Upon drying, the plates were activated in an oven for 1h at 110 degrees just before use. The active fraction was dissolved in appropriate solvent system (Methanol) and streaked on the plate to form a band. The plate was lowered into a preparative thin layer chromatographic tank that was previously loaded with predetermined solvent (Mobile phase) system and saturated with whatman filter paper. Different bands (which represent different pure compounds) were scrapped into different test tubes. Thereafter, the different bands were dissolved in appropriate solvent system (methanol), centrifuged, filtered, concentrated to dryness and stored in a refrigerator until

time of use. Bioassay testing of the different compounds eluted was again carried out by repeating the experiment in section 3.2.14.3.

3.2.14.5 Bioassay-guided preparative thin layer chromatography on the active sub-fraction (purification of fraction 2)

Diabetes again was induced in 12 rats (groups 1-4) by the method of venugopal *et al*., (1998). Fifteen rats were assigned into 5 groups of 3 rats per group. The rats in groups 1 and 2 were treated with 2 mg/kg of the sub-fraction 2 and the rats in groups 3 and 4 were treated with 2 mg/kg glibenclamide and 10 ml/kg distilled water respectively while rats in group 5 were not induced but treated with the vehicle (10 ml/kg distilled water). Thereafter, blood samples were taken 1h, 3 h and 6 h posttreatment for FBG analysis.

3.2.14.6 Characterization and structural elucidation of the active compound(s)

This was done using Nuclear Magnetic Resonance (NMR) spectroscopy (carbon 13 and proton NMR).

Nuclear Magnetic Resonance (NMR) **spectroscopy**

Spectroscopy is the study of the interaction of electromagnetic radiation (EMR) with matter. Nuclear magnetic resonance spectroscopy determines the physical and chemical properties of atoms or molecules and can provide detailed information about the structure, dynamics, reaction states and chemical environment of molecules (Shah *et al.,* 2006). It is the study of interaction of radio frequency (RF) of the EMR with unpaired nuclear spins in an external magnetic field to extract structural information about a given sample. It is routinely used by chemists to study chemical structure of simple molecules using simple one dimensional technique (1D-NMR). Two dimensional techniques (2D-NMR) are used to determine the structure of more complicated molecules (Abraham *et al.,* 1988).

3.2.14.7 Statistical analyses

Statistical package for social sciences version 20 was employed. One-Way Analysis of Variance (ANOVA) was used to compare the means of some of the parameters and their difference separated using Duncans Multiple Range test while Data on fasting blood sugar levels and glycosylated haemoglobin were correlated using pearson parametric correlation. P values <0.05 were considered significant.

CHAPTER FOUR
RESULTS

4.1 Percentage yield of the extract

The percentage yield of the extract was 12.5 %.

4.2 Acute toxicity

The result of acute toxicity test of the extract is presented in table 10. Treatment of rats orally with varying doses (500, 1000, 2000 3,000, 4000 and 5000 mg/kg) of the methanol root bark extract of *Cussonia arborea* did not result in toxicity signs nor deaths of the treated animals (Table 10). The LD_{50} therefore was not obtained.

4.3 Phytochemical test result

Table 11 shows the result of phytochemical screening of the extract of *C. arborea*. The result of the phytochemical studies of the methanol root bark extract of *Cussonia arborea* revealed the presence of saponins and terpenes in very high quantity, glycosides, alkaloids, flavonoids, in relatively high amount, tannins, were found in moderate concentrations.

4.4 The percentage antioxidant activities of the methanol root bark extract of *Cussonia arborea* using FRAP assay model

The result of the FRAP assay indicates that the antioxidant activity of the methanol root bark extract of *Cussonia arborea* increased with increase in the concentration of the extract with optimum activity of 75 % at the concentration of 400 µg/ml. This was presented in figure 4.

Table 10: Result of acute toxicity test using varying doses of the methanol root bark extract of *Cussonia arborea* on rats.

GROUP	DOSE (mg/kg)	Signs of Toxicity/Death
1	500	**None**
2	1000	**None**
3	2000	**None**
4	3000	**None**
5	4000	**None**
6	5000	**None**
7	**Distilled water**	**None**

Table 11: Phytochemistry of the methanol root bark extract of *Cussonia arborea*

Phytochemical constituents	**Tests**	**Concentration**
Saponins	Froathing	+++
	Emulsifying	+++
Glycosides	Sulphuric acid +Fehlings I and II	++
Tannins	Lead acetate	+
	Ferric chloride	+
	Sulphuric acid	+
Alkaloids	Wagner	+
	Meyer	++
	Dragendorff`s	++
Flavonoids	Sodium hydroxide	++
Terpenes	**Acetic acid anhydride+ chloroform + sulphuric acid**	+++
	+ **moderate**	
	++ **high**	
	+++ **very high**	

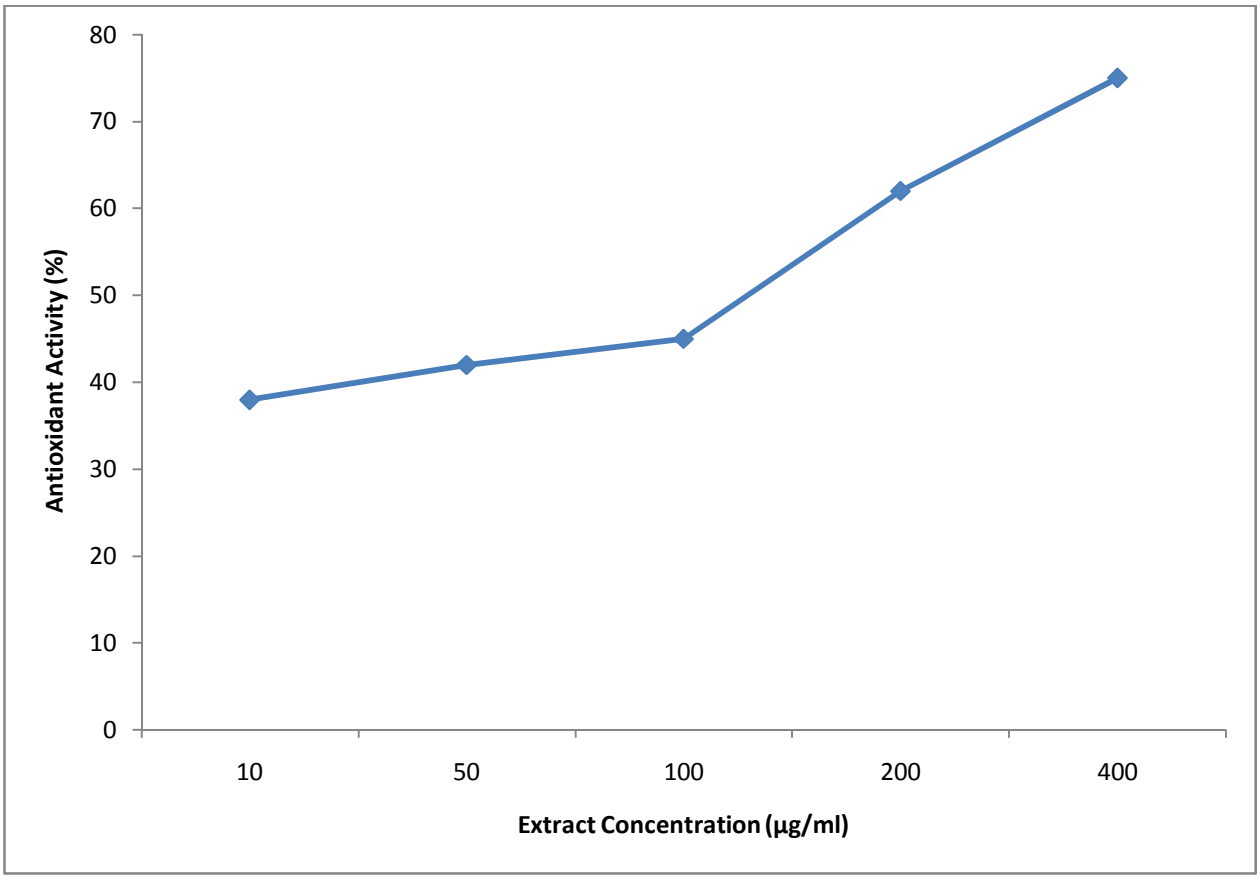

Figure 4: The percentage antioxidant activities of the methanol root bark extract of *Cussonia arborea* using FRAP assay model

4.5 The antioxidant activity of the methanol root bark extract of *Cussonia arborea* at different Concentrations using DPPH photometric assay method

The antioxidant test using DPPH assay (**Figure 5**) indicated that both the extract and the ascorbic acid/vitamin C (positive control) exhibited concentration-dependent effect on antioxidant activity with optimum activities of 74% and 92% respectively at the concentration of 400 µg/ml.

4.6 Effects of acute administration of *Cussonia arborea* root bark extract on Fasting blood glucose levels of alloxan-induced diabetic rats

The result of the acute anti diabetic study (**Table 12**) shows that the fasting blood glucose levels (FBG) of the rats in group 6 were significantly ($p< 0.05$) lower than those in other groups following induction. Six hours post treatment, the FBS levels of group one rats were significantly ($p<0.05$) lower than that of the negative control rats (Group 5) but statistically comparable to that of the normal control rats and group 4 rats till the end of the experiment (24 h).

4.7 Effect of *Cussonia arborea* extract on FBG of normoglycaemic rat (Oral glucose tolerance test)

The result indicates that 30 mins post glucose load/challenge, the sugar levels of the rats increased significantly ($p<0.05$) (**Table 13**). The sugar levels of the group 2 rats (treated with 250 mg/kg of the extract) was significantly ($p<0.05$) reduced compared to that treated with distilled water but was statistically comparable to the group treated with glibenclamide, 180 mins post glucose challenge.

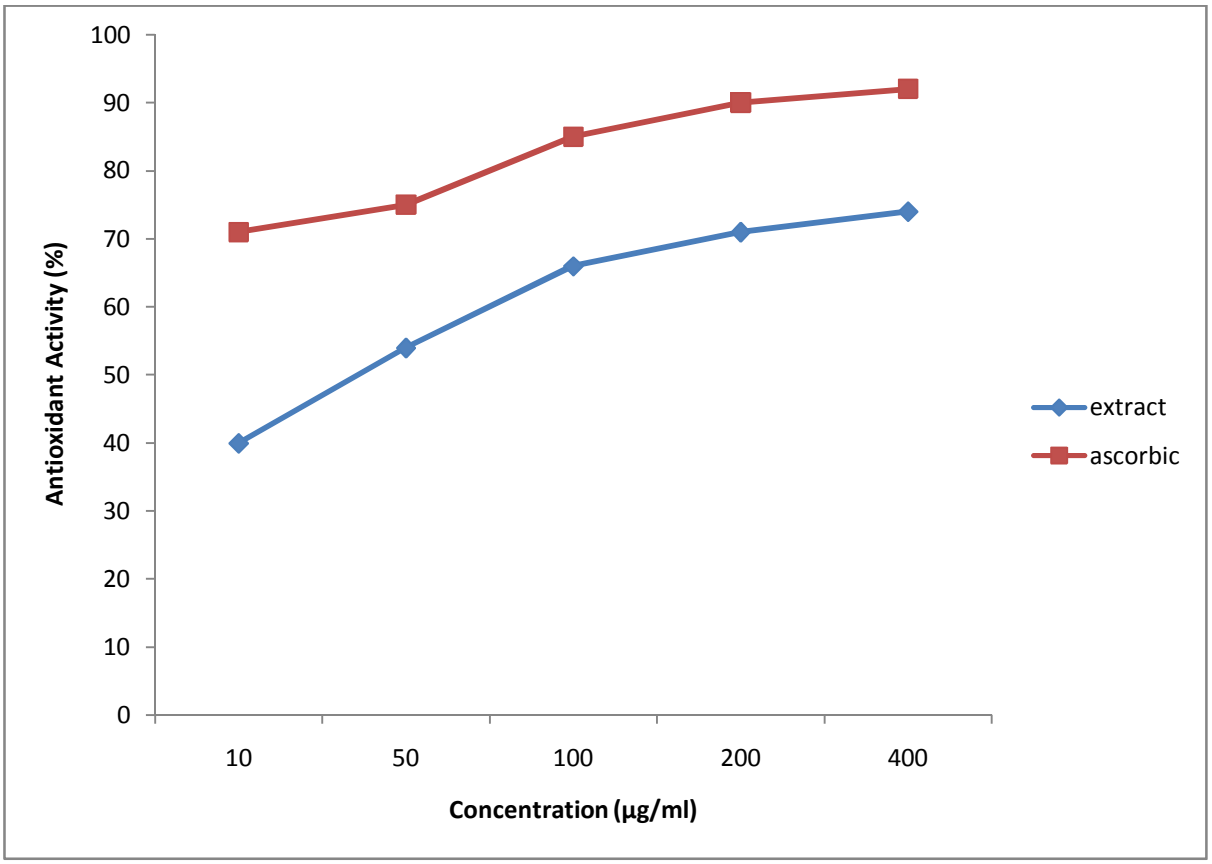

Figure 5: The antioxidant activity of the methanol root bark extract of *Cussonia arborea* at different Concentrations using DPPH photometric assay method

Table 12: Effects of acute administration of *Cussonia arborea* root bark extract on Fasting blood glucose (mg/dl) levels of alloxan-induced diabetic rats

Different superscripts along the same column indicate significant difference at $p<0.05$

Group 1: Normoglycaemic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* + glucose (2000 mg/kg)

Group 2: Normoglycaemic rats treated with 500 mg/kg of methanol root bark extract of *Cussonia arborea* + glucose (2000 mg/kg)

Group 3: Normoglycaemic rats treated with 1000 mg/kg of methanol root bark extract of *Cussonia arborea* + glucose (2000 mg/kg)

Group 4: Normoglycaemic rats treated with 2mg/kg glibenclamide + glucose (2000 mg/kg)

Group 5: Normoglycaemic rats treated with 10 ml/kg of distilled water + glucose (2000 mg/kg)

4.8: Effects of chronic administration of *Cussonia arborea* root bark extract on Fasting blood glucose levels of alloxan-induced diabetic rats

The FBS of all the rats in groups 1, 2, 3, 4 and 5 were significantly ($p< 0.05$) higher than that of the group 6 rats (Normal control) post induction. On day 14 post treatment, the FBS levels of groups 2 and 4 rats were significantly ($p<0.05$) lower than those of the group 5 rats but statistically comparable to that of the group 6 rats (Normal control). These two groups 2 and 4 consistently compared very well with the normal control rats throughout the 84 day duration of the study (**Table 14**).

4.9: Effects of different fractions of *Cussonia arborea* on the fasting blood glucose levels of alloxan induced diabetic rats

The FBS levels of the rats treated with fraction 2 were significantly ($p< 0.05$) lower than the FBS of the diabetic untreated rats (Group 5) 3 h and 6 h post treatment but was statistically comparable to that of the normal control rats and to that of the rats treated with glibenclamide (Group 4 rats) (**Table 15**).

4.10: Effect of subfraction 2 of *Cussonia arborea* root bark extract on the fasting blood glucose levels of alloxan-induced diabetic rats

The FBG levels of the rats treated with subfraction 1 of the fraction 2 ($Subf2_1$) showed a significant ($p< 0.05$) reduction when compared with the diabetic untreated (group 4) rats 3 h and 6 h post treatment but was statistically comparable to those of the rats treated with standard drug (Glibenclamide) and normal control rats (**Table 16**).

Different superscripts along the same column indicate significant difference at $p<0.05$

4.11: Glycosylated haemoglobin {HbA_{1c}} values of alloxan-induced diabetic rats treated with methanol root bark extract of *Cussonia arborea*

The glycosylated haemoglobin values of group 2 rats (125 mg/kg of extract) were significantly ($p<0.05$) lower than that of the group 5 rats (negative control) but was statistically comparable ($p> 0.05$) to those of group 6 rats (Normal control) and to those treated with standard drug (Glibenclemide) 42 days post treatment. On days 56 and 84, all the treatment groups showed significantly ($p< 0.05$) lower values of glycosylated hemoglobin when compared with the negative control groups.

The correlation between the glycosylated hemoglobin and fasting glucose levels indicate that they significantly ($p<0.01$) correlate with each other with r^2 value of 0.914 on day 84 post-treatment. (Mean HbA1c in % (Mean +SEM): 7.328± 1.97; Mean FBS in mg/dl (Mean +SEM: 123.94± 77.83; Pearsons correlation value (0.910) significant at 0.01 level (2 ï tailed); r^2= 0.914) (**Figure 6**).

4.12: Effects of chronic administration of *Cussonia arborea* root bark extract on the activity of aspartate aminotransferase of alloxan-induced diabetic rats

The result indicates that AST activities of the rats in groups 2 and 4 were comparable to those of the group 6 (Normal control) but were found to be significantly ($p< 0.05$) lower than those of the rats in groups 1, 3 and 5 on day 28 post treatment. On day 56, the AST activity of the rats in group 1 compared well with that in group 2 but was still higher than that of the normal control while on day 84, the AST activities of the rats in groups 1, 2 and 4 were comparable to that of the normal control. However, those of the groups 3 and 5 remained significantly ($p< 0.05$) higher than the normal control.

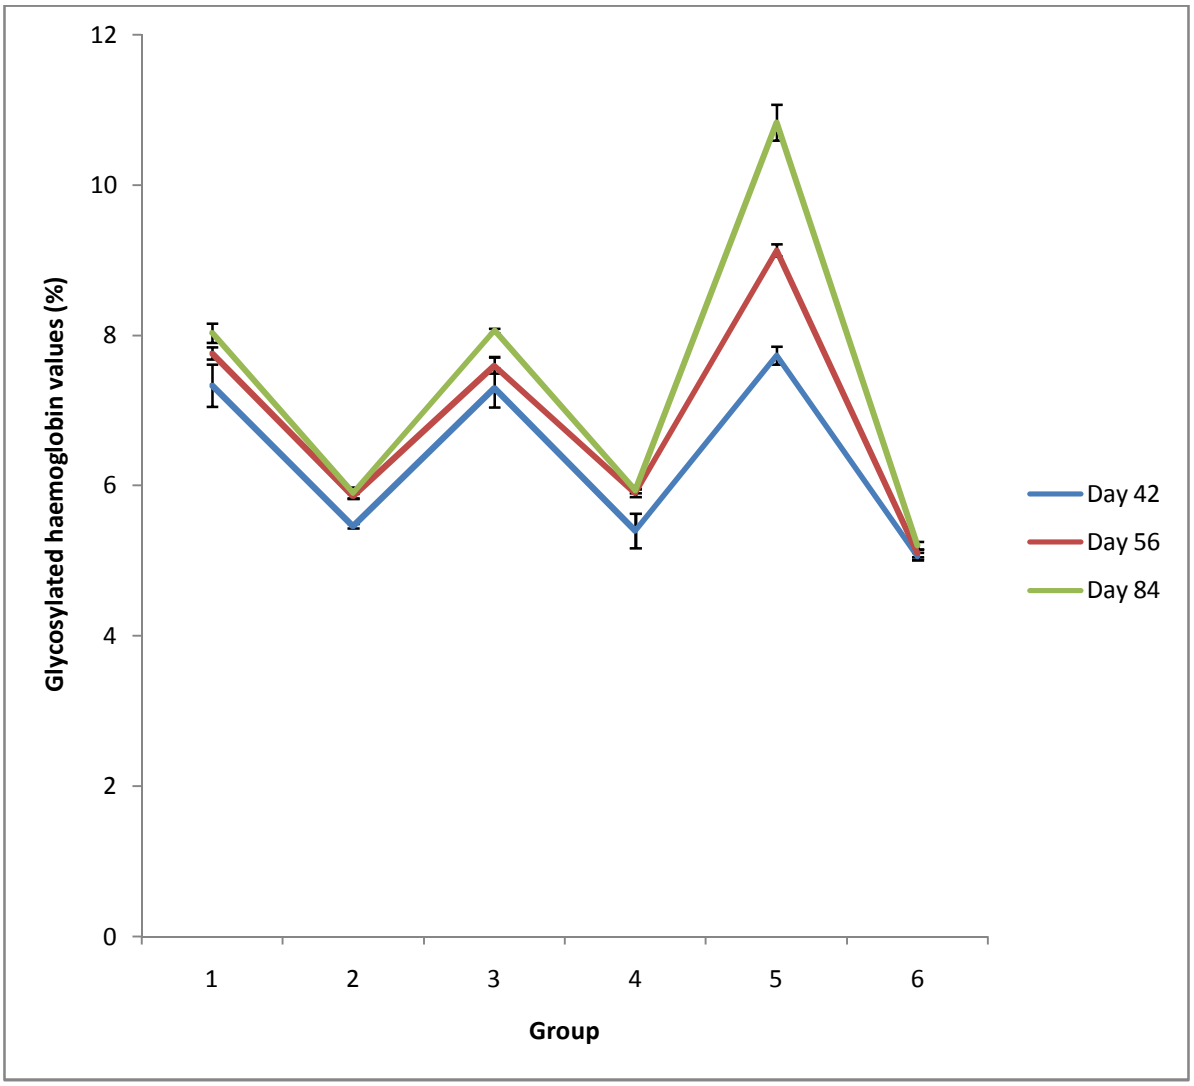

Figure 6: Glycosylated haemoglobin {HbA1c (%)} values of alloxan-induced diabetic rats treated with methanol root bark extract of *Cussonia arborea*

Table 17: Effects of chronic administration of *Cussonia arborea* root bark extract on the activity of aspartate aminotransferase (U/L) of alloxan-induced diabetic rats

GROUP	DAY 28	DAY 56	DAY 84

Different superscripts along the same column indicate significant difference at $p<0.05$

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.13: Effects of chronic administration of *Cussonia arborea* root bark extract on the activity of alanine aminotransferase of alloxan-induced diabetic rats

On day 28 post treatment, the ALT activities of the rats in groups, 1 and 3 were statistically comparable (P>0.05) to those of the normal control (Group 6 rats) but was significantly (P < 0.05) lower than the ALT activities of the rats in group 5 (negative control). On day 56, the ALT activities of the rats in groups 2 and 4 compared very well to those in group 6 while those of the rats in group 5 remained significantly higher than those of all the groups till the end of the experiment. On day 84, ALT activities of the rats in all the groups were statistically comparable (p> 0.05) but lower than those of the group 5 (**Table 18**).

4.14: Effects of chronic administration of *Cussonia arborea* root bark extract on total serum Cholesterol of alloxan-induced diabetic rats

Total cholesterol levels of the rats in group 5 were significantly (p<0.05) higher than the cholesterol level of the rats in group 6 (Normal control) and those of the other groups across the treatment periods. On days 56 and 84 post treatment, the total cholesterol levels of groups 2 and 4 rats were statistically comparable (p> 0.05) to the normal control rats but significantly (p<0.05) lower than those of the groups 1 and 3 rats (**Table 19**).

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

Table 19: Effects of chronic administration of *Cussonia arborea* root bark extract on total serum Cholesterol (mg/dl) of alloxan-induced diabetic rats

Group	DAY 28	DAY 56	DAY 84
1	149.48±1.04^{c}	148.83±1.47^{b}	142.92± 1.27^{b}
2	141.20± 0.92^{b}	135.33± 1.74^{a}	133.04± 1.49^{a}
3	149.70± 1.39^{c}	162.79± 3.84^{c}	153.49± 1.55^{c}
4	135.22± 3.28^{ab}	134.68±1.73^{a}	134.08± 1.41^{a}
5	167.86± 0.37^{d}	180.11 ± 1.65^{d}	168.47± 0.52^{d}
6	130.37± 4.03^{d}	130.41 ± 2.95^{a}	131.00± 1.20^{a}

Different superscripts along the same column indicate significant difference at $p<0.05$

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.15: Effects of chronic administration of *Cussonia arborea* root bark extract on serum triglycerides (mg/dl) of alloxan-induced diabetic rats

The table indicates that the triglyceride levels of the rats in group 6 (Normal rats) were statistically lower than those in other groups on day 28 post treatment. However, on day 56 and 84, it was comparable ($p > 0.05$) to those in groups 2 and 4. The triglyceride levels of the rats in group 5 were significantly higher than those of the other groups throughout the experiment period (**Table 20**).

4.16: Effects of chronic administration of *Cussonia arborea* root bark extract on high density lipoprotein of alloxan-induced diabetic rats

The results of the high density lipoprotein (HDL) indicate that the HDL levels of rats in group 2 were significantly ($p < 0.05$) higher than those of the rats in groups 1,3 and 5 but were comparable to the triglyceride levels of rats in group 4 across the treatment periods (**Figure 7**).

4.17: Effects of chronic administration of *Cussonia arborea* root bark extract on very low density lipoprotein of alloxan-induced diabetic rats

Table 21 shows that the VLDL levels of rats in group 2 were significantly ($p < 0.05$) lower than those of the rats in groups 1, 3 and 5 on days 28, 56 and 84 but comparable ($p > 0.05$) to those in group 6 (Normal control rats). The VLDL levels of rats in group 5 were significantly ($p < 0.05$) higher than those of the other groups throughout the period of the experiment (**Table 21**).

Table 20: Effects of chronic administration of *Cussonia arborea* root bark extract on serum triglycerides (mg/dl) of alloxan-induced diabetic rats

Group	DAY 28	DAY 56	DAY 84

Different superscripts along the same column indicate significant difference at $p<0.05$

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.18: Effects of chronic administration of *Cussonia arborea* root bark extract on low density lipoprotein of alloxan-induced diabetic rats

Low density liproprotein levels of the rats in groups 2 and 4 were statistically comparable to those of the normal control (Group 6) rats and significantly ($p< 0.05$) lower than those in groups 1 and 3 throughout the experimental period of 84 days (**Table 22**).

4.19: Effects of chronic administration of *Cussonia arborea* root bark extract on serum total protein of alloxan-induced diabetic rats

The total protein level of group 5 rat shows a significant ($p< 0.05$) reduction from those of the normal control rats and other group on days 56 and 84 while the total protein levels of the rats in group 2 were statistically comparable to those of the normal control rats on these days (**Table 23**).

4.20: Effects of chronic administration of *Cussonia arborea* root bark extract on serum total albumin of alloxan-induced diabetic rats

On day 28, the albumin levels of the rats in all the groups were statistically comparable. Albumin levels of rats in groups 1, 2, 4 and 6 also compared very well on day 56 but were significantly higher than those of group 5 rats. However on day 84, the albumin levels of the rats in group 1, 3, 4 and 5 were comparable but significantly ($p< 0.05$) lower than those of groups 2 and 6 (**Table 24**).

Table 22: Effects of chronic administration of *Cussonia arborea* root bark extract on low density lipoprotein (mg/dl) of alloxan-induced diabetic rats

Group	DAY 28	DAY 56	DAY 84

Different superscripts along the same column indicate significant difference at $p<0.05$

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.21: Effects of chronic administration of *Cussonia arborea* root bark extract on serum globulin of alloxan-induced diabetic rats

Groups 1, 2, 4 and 5 rats have comparable globulin levels on day 28. This was significantly ($p< 0.05$) higher than those of the normal control rats. The globulin levels of the normal control rats (Rats in group 6) were significantly ($p< 0.05$) higher than those of the negative control rats (group 5 rats) but where statistically comparable to those of the other groups (**Table 25**).

4.22: Effects of chronic administration of *Cussonia arborea* root bark extract on serum albumin: globulin ratio of alloxan-induced diabetic rats

There was no significant differences except on the day 28 when the rats in group 1 appear to have a significantly ($p< 0.05$) lower albumin: globulin ratio compared to normal control rats (**Table 26**).

4.23: Effects of chronic administration of *Cussonia arborea* root bark extract on blood urea nitrogen (BUN) (mg/dl) of alloxan-induced diabetic rats

The elevated BUN levels of group 5 rats were significantly ($p< 0.05$) higher than those of the rats in other groups including the normal control rats throughout the treatment period. The BUN of rats in groups 1, 2 and 4 were comparable to that of the normal control rats throughout the duration of the experiment (**Figure 8**).

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.24: Effects of chronic administration of *Cussonia arborea* root bark extract on serum creatinine of alloxan-induced diabetic rats

The creatinine levels of the rats in group 5 were significantly ($p<0.05$) elevated compared to that of the other groups throughout the period of the experiment. On day 28, groups 1, 2, 3 and 4 ratsô creatinine compared very well among one another but were significantly ($p<0.05$) higher than that of the normal control rats. The creatinine levels of groups 2, and 4 rats were statistically comparable to that of the group 6 rats on days 56 and 84 (**Table 27**).

4.25: Effects of chronic administration of *Cussonia arborea* root bark extract on serum total bilirubin of alloxan-induced diabetic rats

The total bilirubin levels of the rats in group 5 were significantly ($p< 0.05$) elevated compared to the normal control rats and other groups throughout the experimental period. Groups 2, and 4 rats have comparable ($p> 0.05$) total bilirubin values as seen on day 56. The total bilirubin levels of groups 1, 2 and 4 rats compare very well among one another on day 84 but were significantly ($p< 0.05$) higher than that of the normal control (**Table 28**).

4.26: Effects of chronic administration of *Cussonia arborea* root bark extract on serum conjugated bilirubin of alloxan-induced diabetic rats

The conjugated bilirubin levels of rats in group 5 were significantly ($p<0.05$) different from those of the other groups on day 28 but compared very well with 1, 3, 4 and 5 on days 56 and 84 post treatment. On day 56, the conjugated bilirubin levels of group 2 rats were significantly ($p<0.05$) higher than that of the groups 1, 3 and 5 but statistically comparable to those of the normal control rats (**Figure 9**).

4.27: Effects of chronic administration of *Cussonia arborea* root bark extract on serum unconjugated bilirubin of alloxan-induced diabetic rats

Unconjugated bilirubin levels of the normal control rats compared very well with those of the rats in groups 2 and 4 on day 28 but differed significantly ($p< 0.05$) from those of the other groups. On days 56 and 84, the unconjugated bilirubin levels of the normal control rats were significantly ($p< 0.05$) lower than those of other groups (**Table 29**).

4.28: Effects of chronic administration of *Cussonia arborea* root bark extract on the ratios of serum AST: ALT activities of alloxan-induced diabetic rats

The AST: ALT ratio of the rats in groups 2 and 4 compared with those of the rats in group 6 (Normal control) throughout the experiment but were significantly ($p< 0.05$) higher than those of the negative control group on day 28 (**Table 30**).

4.29: Effects of chronic administration of *Cussonia arborea* root bark extract on BUN: Creatinine ratio of alloxan-induced diabetic rats

The Blood urea nitrogen: Creatinine ratio of the rats in group 5 (Negative control) were statistically comparable to that of the normal control rats and to other rats in other groups but was significantly ($p<0.05$) higher than those of the group 4 rats on day 28 post treatment. Groups 1, 2 and 4 ratsô BUN: creatinine ratio were statistically comparable to the normal control rats on day 84 but were significantly ($p< 0.05$) lower than those of the other groups (**Table 31**).

Different superscripts along the same column indicate significant difference at $p<0.05$

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.30: Effects of chronic administration of *Cussonia arborea* root bark extract on red blood cell count of alloxan-induced diabetic rats

The red blood cell counts of the normal control rats (Group 6) were significantly ($p< 0.05$) higher than those of the other groups on days 28 and 56 post treatment. On day 84 however, the RBC counts of rats in groups 2 and 4 were statistically comparable ($p> 0.05$) to that of the normal control rats (**Table 32**).

4.31: Effects of chronic administration of *Cussonia arborea* root bark extract on total haemoglobin concentration (g/dL) of alloxan-induced diabetic rats

The total haemoglobin of diabetic untreated rats (Group 5) was significantly ($p< 0.05$) lower than the total haemoglobin of other rats in other group throughout the experiment. The rats in groups 2 and 4 have their total haemoglobin values statistically comparable ($p> 0.05$) to those of the normal control rats (Group 6) on days 56 and 84 post treatment (**Table 33**).

4.32: Effects of chronic administration of *Cussonia arborea* root bark extract on the packed cell volume of alloxan-induced diabetic rats

The packed cell volume of the rats in group 6 was significantly ($p< 0.05$) higher than the negative control (Group 5) and other groups throughout the period of the experiment except on day 84 when the values were statistically comparable ($p> 0.05$) to the packed cell volume value of the rats in group 2 (**Figure 10**).

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

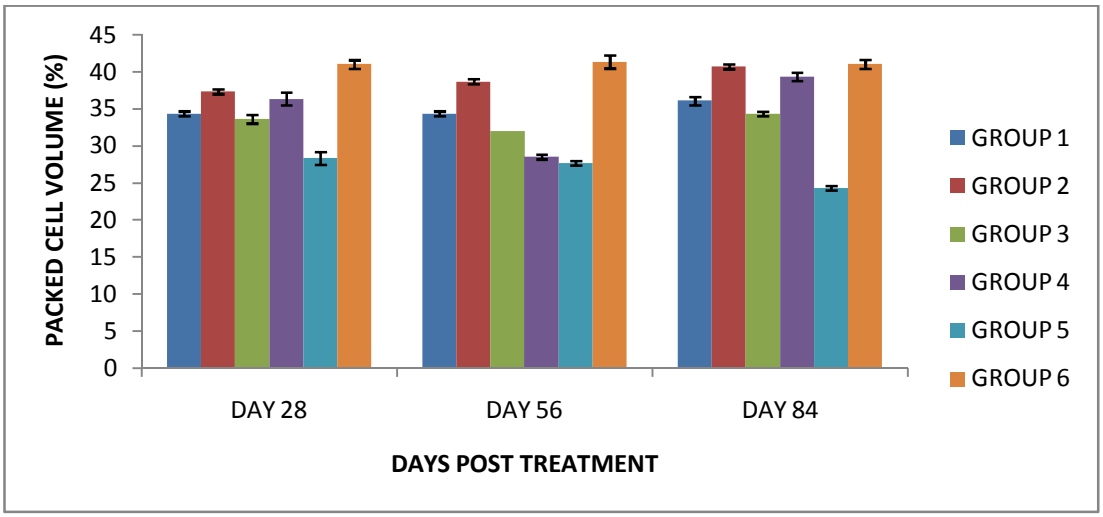

Fig. 10: Effects of chronic administration of *Cussonia arborea* root bark extract on the packed cell volume (%) of alloxan-induced diabetic rats

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.33: Effects of chronic administration of *Cussonia arborea* root bark extract on mean corpuscular volume of alloxan-induced diabetic rats

The mean corpuscular volume of groups 2 and 4 rats were statistically comparable ($p > 0.05$) to those of the negative and normal control groups on day 28. On days 56 and 84, the MCV values of groups 2, 3, 4 and 6 were statistically comparable to one another but were significantly lower than that of the negative control group (**Table 34**).

4.34: Effects of chronic administration of *Cussonia arborea* root bark extract on the mean corpuscular haemoglobin concentration of alloxan-induced diabetic rats

No significant differences were observed among all the groups throughout the duration of the experiment (**Table 35**).

4.35: Effects of chronic administration of *Cussonia arborea* root bark extract on the mean corpuscular haemoglobin of alloxan-induced diabetic rats

The mean corpuscular haemoglobin of all the rats in group 1,2 ,3, and 4 were significantly ($p < 0.05$) lower than that of the group 5 (Negative control rats) but statistically comparable ($p > 0.05$) to that of group 6 rats on days 56 and 84 post treatment (**Table 36**).

4.36: Effects of chronic administration of *Cussonia arborea* root bark extract on total White blood cell count of alloxan-induced diabetic rats

The total white blood cell counts of rats in groups 1 and 2 were significantly ($p < 0.05$) higher than that of the negative control group but were statistically comparable ($p > 0.05$) to that of the normal control rats on days 56 and 84 post treatment (**Table 37**).

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.37: Effects of chronic administration of *Cussonia arborea* root bark extract on lymphocyte count of alloxan-induced diabetic rats

On day 28, the lymphocytes of groups 1, 2, 3 and 4 rats were significantly ($p<0.05$) higher than that of group 5 rats. On days 56 and 84 however, they were statistically comparable (**Table 38**).

4.38: Effects of chronic administration of *Cussonia arborea* root bark extract on neutrophil count of alloxan-induced diabetic rats

No significant changes were observed in the neutrophil counts of all the rats in the treatment groups throughout the duration of the experiment. The neutrophil count of the rats in group 5 was significantly ($p< 0.05$) higher than that of the normal control rats except on day 84 (**Table 39**).

4.39: Effects of chronic administration of *Cussonia arborea* root bark extract on Basophil count of alloxan-induced diabetic rats

No significant changes were observed throughout the duration of the experiment (**Table 40**).

4.40: Effects of chronic administration of *Cussonia arborea* root bark extract on Eosinophil count of alloxan-induced diabetic rats

No significant changes were observed except on the day 84, where the eosinophil counts of group 6 rats were significantly ($p< 0.05$) higher than that of the negative control rats (Group 5) **(Table 41).**

4.41: Effects of chronic administration of *Cussonia arborea* root bark extract on Monocyte (%) count of alloxan-induced diabetic rats

No significant changes were observed in the monocyte counts of the rats in all the groups across the treatment period except for rats in group 3 which had a significantly ($p< 0.05$) higher monocyte count on day 28 when compared with the negative control group (**Table 42**).

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.42: Effects of chronic administration of *Cussonia arborea* root bark extract on plasma malondialdehyde of alloxan-induced diabetic rats

The malondialdehyde level of the rats in group 5 (Negative control) was significantly ($p< 0.05$) higher than that of the normal control rats and other groups throughout the experimental period. The rats in group 2 have a statistically comparable ($p> 0.05$) MDA value with the normal control rats on days 56 and 84 post treatment (**Table 43**).

4.43: Effects of chronic administration of *Cussonia arborea* root bark extract on the activities of superoxide dismutase (U/L) of alloxan-induced diabetic rats

The superoxide dismutase activities of the rats in group 6 (Normal control) were significantly ($p< 0.05$) higher than the negative control group and other groups on day 28 post treatment. On days 56 and 84 post treatment however, the SOD activity of the rats in group 2 were statistically comparable to that of the normal control rats but were significantly ($p< 0.05$) higher than that of the other groups. On day 84, the SOD activity of group 4 rats were statistically comparable to both the normal control group and the group 2 rats (**Table 44**).

4.44: Effects of chronic administration of *Cussonia arborea* root bark extract on serum reduced gluthatione (mg/dL) of alloxan-induced diabetic rats

The reduced glutathione values of the normal control rats were significantly ($p<0.05$) higher than that of the negative control rats throughout the period of the experiment. On day 84 post treatment however, the reduced glutathione levels of the groups 2 and 4 rats were statistically comparable ($p> 0.05$) with that of the normal control rats (**Figure 11**).

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control

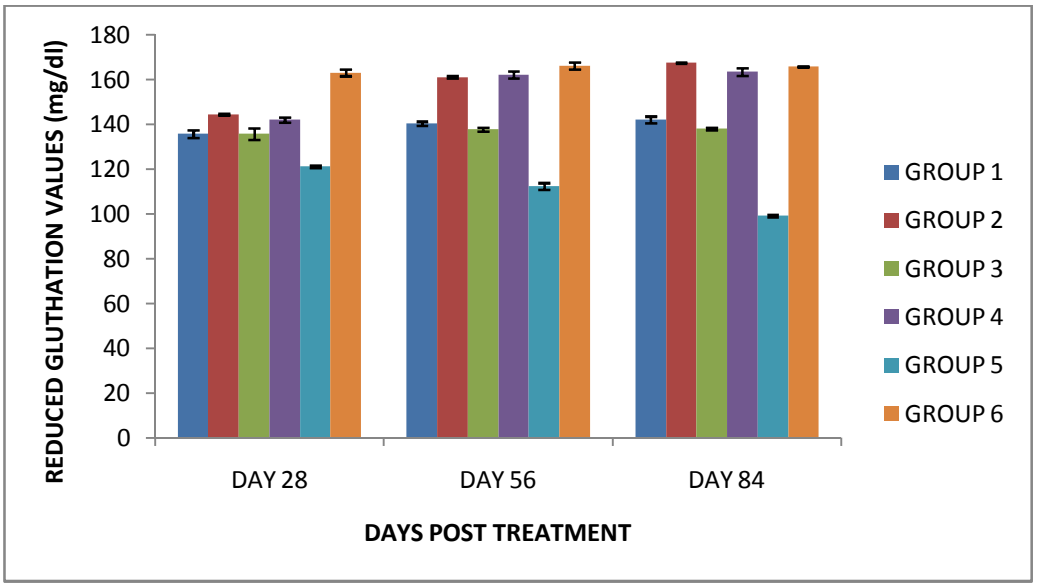

Fig 11: Effects of chronic administration of *Cussonia arborea* root bark extract on serum reduced gluthatione (mg/dL) of alloxan-induced diabetic rats

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.45: Effects of chronic administration of *Cussonia arborea* root bark extract on catalase activity of alloxan-induced diabetic rats

The catalase activity of the negative control rats were significantly ($p< 0.05$) lower than that of the other groups throughout the experimental period. On day 84 post treatment, the catalase activity of the normal control rats and that of the group 2 rats was statistically comparable (**Table 45**).

4.46: Weekly weight (g) changes associated with treatment of alloxan-induced diabetic rats with *Cussonia arborea* extract

The weights of the rats on week zero were all statistically comparable ($p> 0.05$). On week 2 post treatment, the weight of the group 5 rats were significantly ($p< 0.05$) lower than those of the other rats in other groups while the mean weight of the rats in group 6 was significantly ($p< 0.05$) higher than that of the other groups. These persisted till the end of the experiment (**Table 46**).

Table 45: Effects of chronic administration of *Cussonia arborea* root bark extract on catalase (U/L) activity of alloxan-induced diabetic rats

Different superscripts along the same row indicate significant difference at $p<0.05$

Group 1: Diabetic rats treated with 62.5 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 2: Diabetic rats treated with 125 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 3: Diabetic rats treated with 250 mg/kg of methanol root bark extract of *Cussonia arborea* for 84 days

Group 4: Diabetic rats treated with 2 mg/kg of glibenclamide for 84 days (Standard control)

Group 5: Diabetic rats treated with 10 ml/kg of distilled water for 84 days (Negative control)

Group 6: Non-diabetic rats treated with 10 ml/kg of distilled water for 84 days (Normal/positive control)

4.47: Pancreas of normal control rats (Group 6) showing normal cells (arrow) of the islet of langerhans

Photomicrograph of the pancreas shows a fully populated islet cell of langerhans. The islet itself is surrounded by the acinar glands of the exocrine pancreas (**Plate 1**).

4.48: Pancreas of Diabetic untreated rats (Group 5) showing depopulation of the islet cells (arrow)

The photomicrograph of pancreas shows a small sized islet of langerhans with sparse population of the islet cells as shown by the arrow (**Plate 2**).

4.49: Pancreas of group 1 rats (Diabetic + 62.5 mg/kg extract) showing moderate population of the islet cells of the langerhans (Arrow)

The photomicrograph shows islet of langerhans of pancreas with moderately populated islet cells. Acinar cells surround the islet of langerhans. It is not as populated as the normal control but it is more populated than that of the negative controlôs (**Plate 3**)

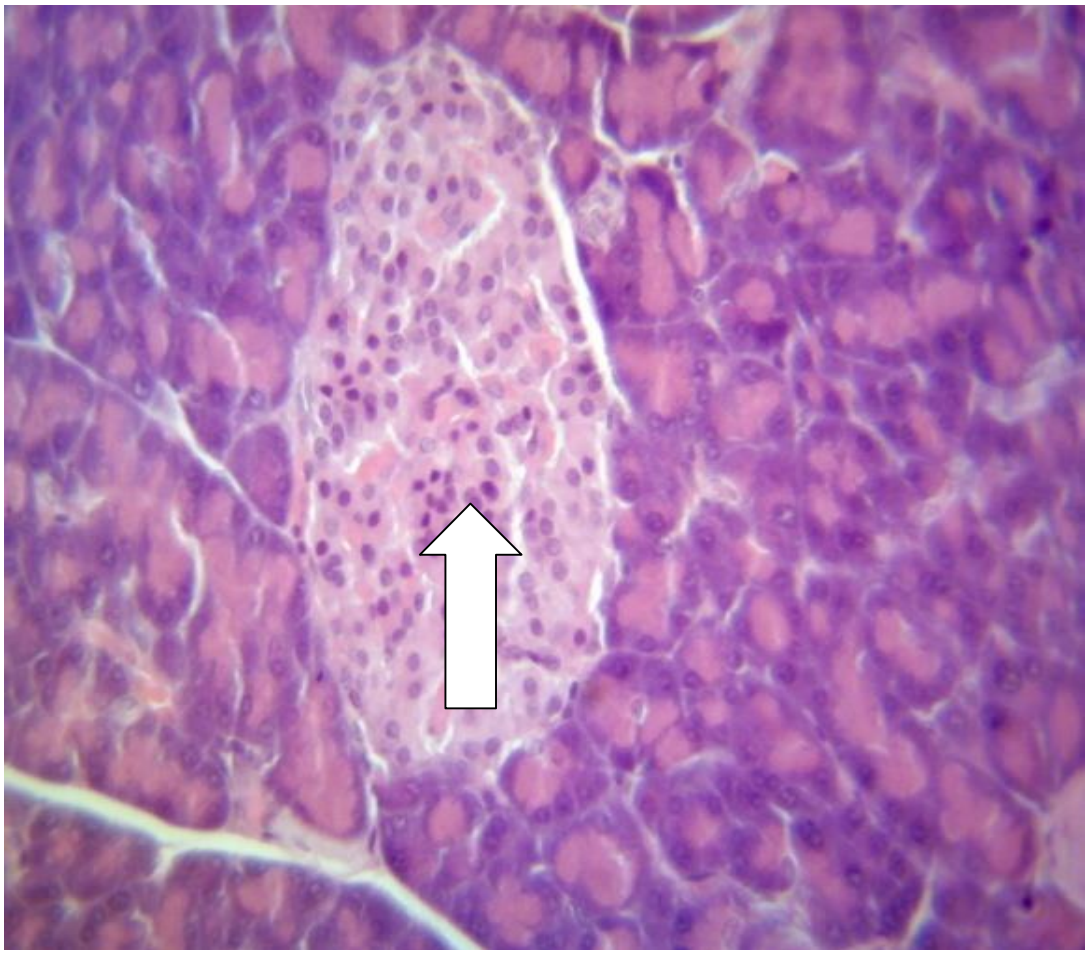

Plate 1: Pancreas of normal control rats (Group 6) showing normal cells (Arrow) of the islet of langerhans (H&E X400)

Plate 2: Pancreas of Diabetic untreated rats (Group 5) showing depopulation of the islet cells (Arrow) (H&E X400)

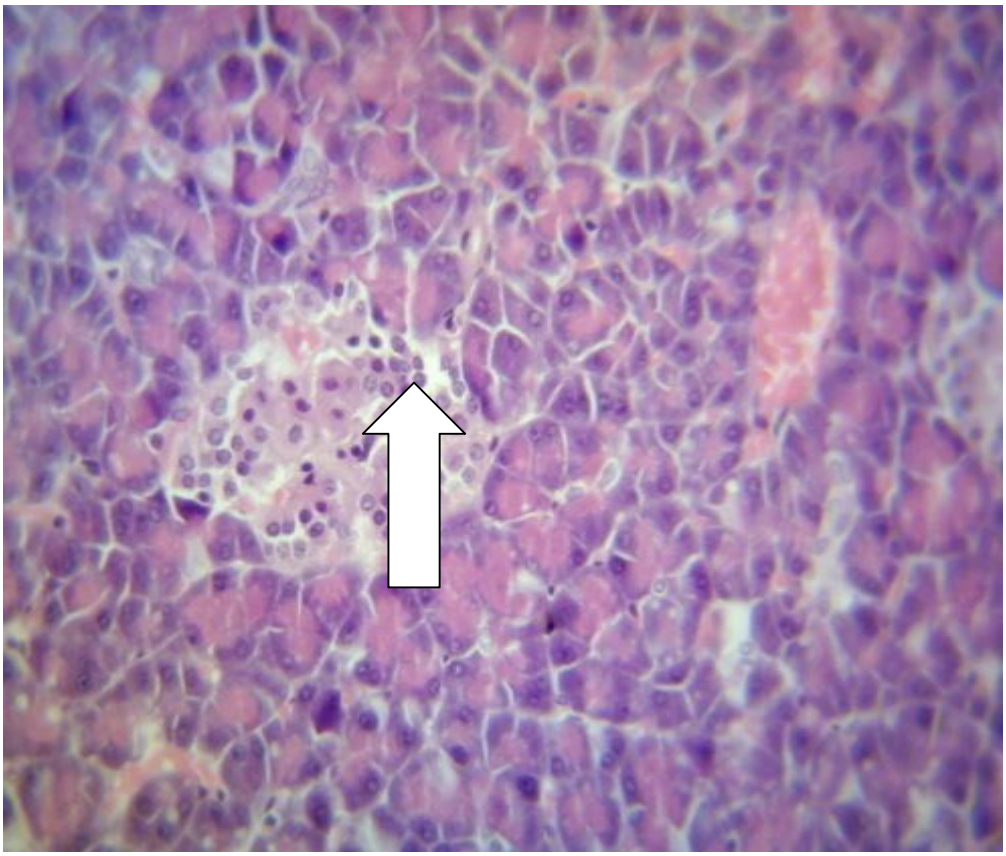

Plate 3: Pancreas of group 1 rats (Diabetic + 62.5 mg/kg extract) showing moderate population of the islet cells of the langerhans (Arrow) (H&E X400)

4.50: Pancreas of group 2 rats (Diabetic + 125 mg/kg extract) showing good population of the islet cells of the langerhans (Arrow)

The photomicrograph shows good population of the islet cells of langerhans as shown by the arrow. The islet cells appear fully populated. The acinar glands of the exocrine pancreas surround the islet (**Plate 4**).

4.51: Pancreas of group 3 rats (Diabetic + 250 mg/kg extract) showing cytoplasmic vacuolations (Arrow) and moderate population of the islet cells of the langerhans

The photomicrograph of the pancreas shows a sizeable islet of langerhans with some islet cells undergoing cytoplasmic vacuolations, a stage in cellular degeneration and necrosis (**Plate 5**).

4.52: Pancreas of group 4 rats (Diabetic + 2 mg/kg glibenclamide) showing good population of the islet cells of the langerhans (Arrows)

The Photomicrograph of pancreas shows densely populated islet cells of langerhans comparable to that seen in normal control rats (**Plate 6**).

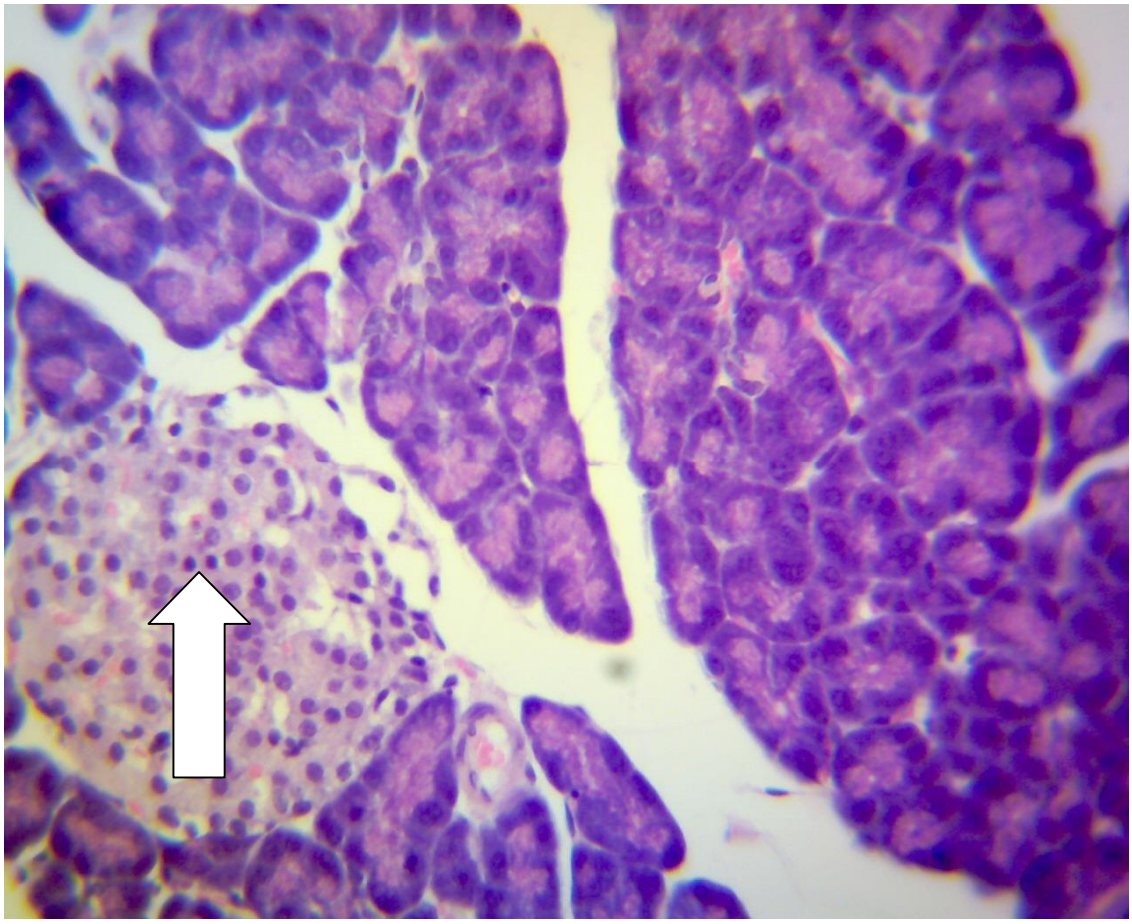

Plate 4: Pancreas of group 2 rats (Diabetic + 125 mg/kg extract) showing good population of the islet cells of the langerhans (Arrow) (H&E X400)

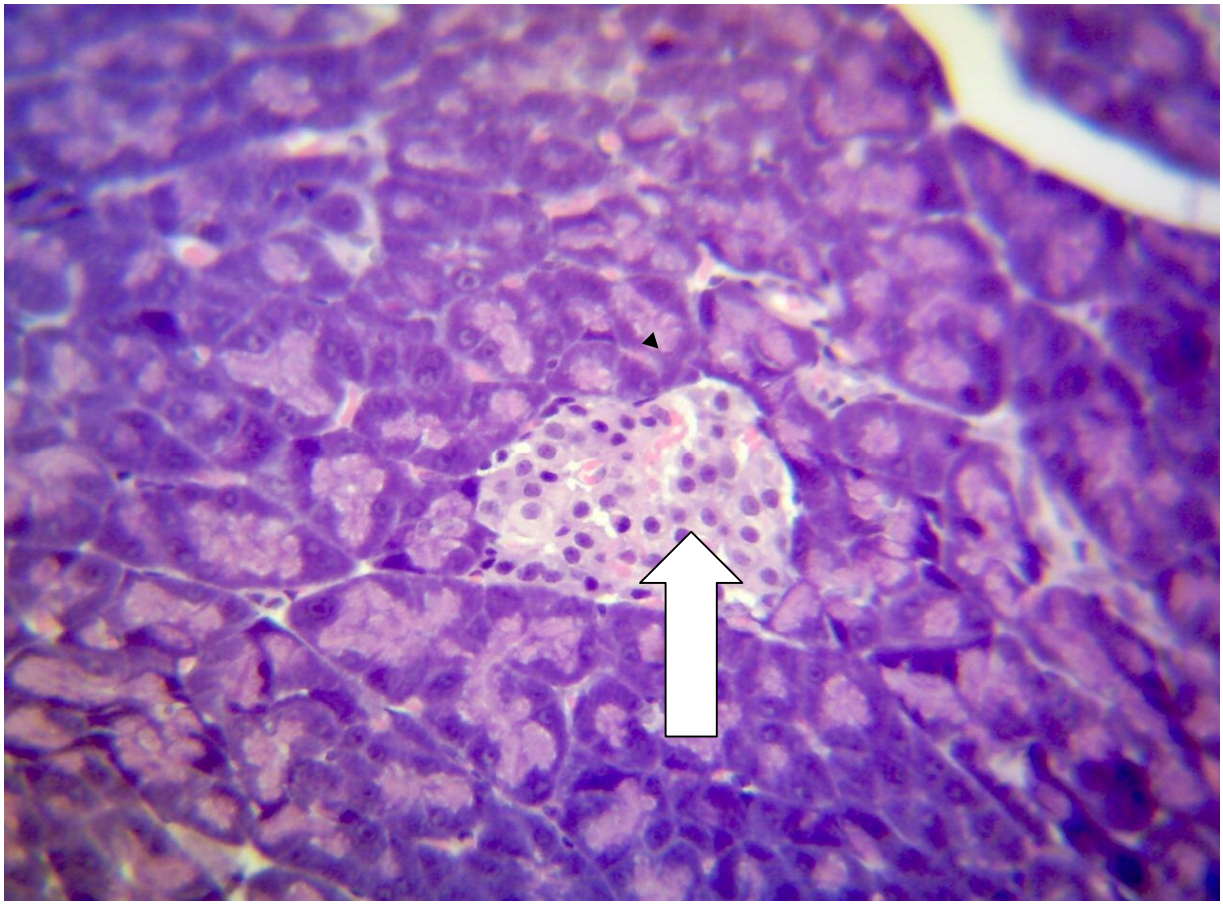

Plate 5: Pancreas of group 3 rats (Diabetic + 250 mg/kg extract) showing cytoplasmic vacuolations (Arrow) and moderate population of the islet cells of the langerhans (H&E X400)

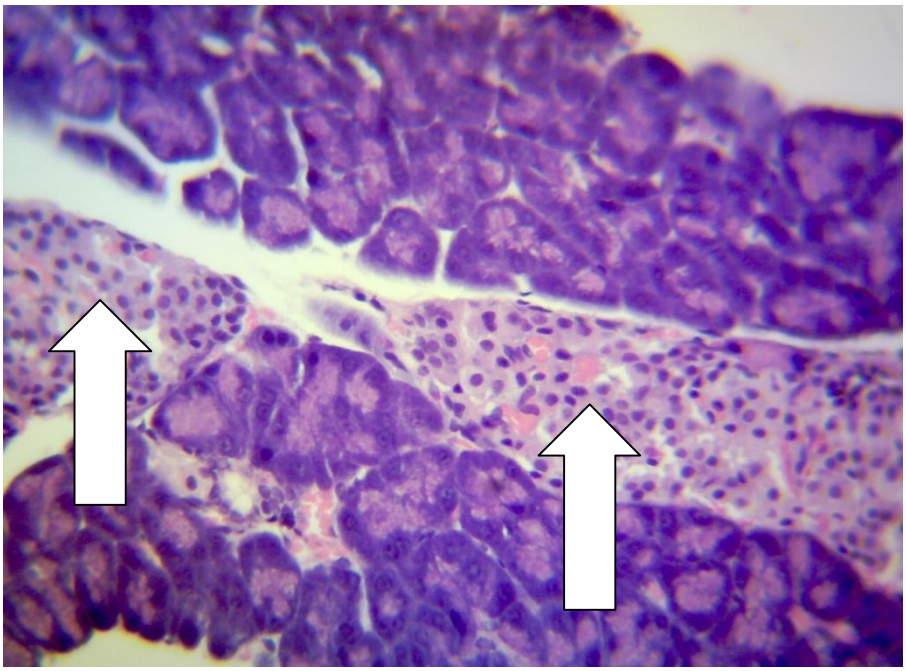

Plate 6: Pancreas of group 4 rats (Diabetic treated with 2 mg/kg glibenclamide) showing good population of the islet cells of the langerhans (Arrows) (H&E X400)

4.53: Kidney of normal control rats (Group 6) showing glomerulus (White arrow) and normal renal tubular epithelial cells (Black arrows)

The photomicrograph of kidney nephrons shows normal glomerulus and renal tubular epithelial cells lining the tubules (**Plate 7**).

4.54: Kidney of rats in group 5 showing erosion of epithelial cells of the renal tubules (White arrows) (H&E X400)

The photomicrograph shows kidney nephrons whose tubular lining epithelial cells are undergoing serious degeneration, erosion and necrosis (**Plate 8**).

4.55: Kidney of group1 rats (Diabetic rats treated with 62.5 mg/kg of extract) showing infiltration with mononuclear cells in the glomerulus (White arrow) and necrosis of the tubular epithelial cells (Black arrows)

This photomicrograph shows kidney nephrons with multifocal erosion of tubular epithelial cells into the lumen. There was also infiltration by mononuclear cells (**Plate 9**).

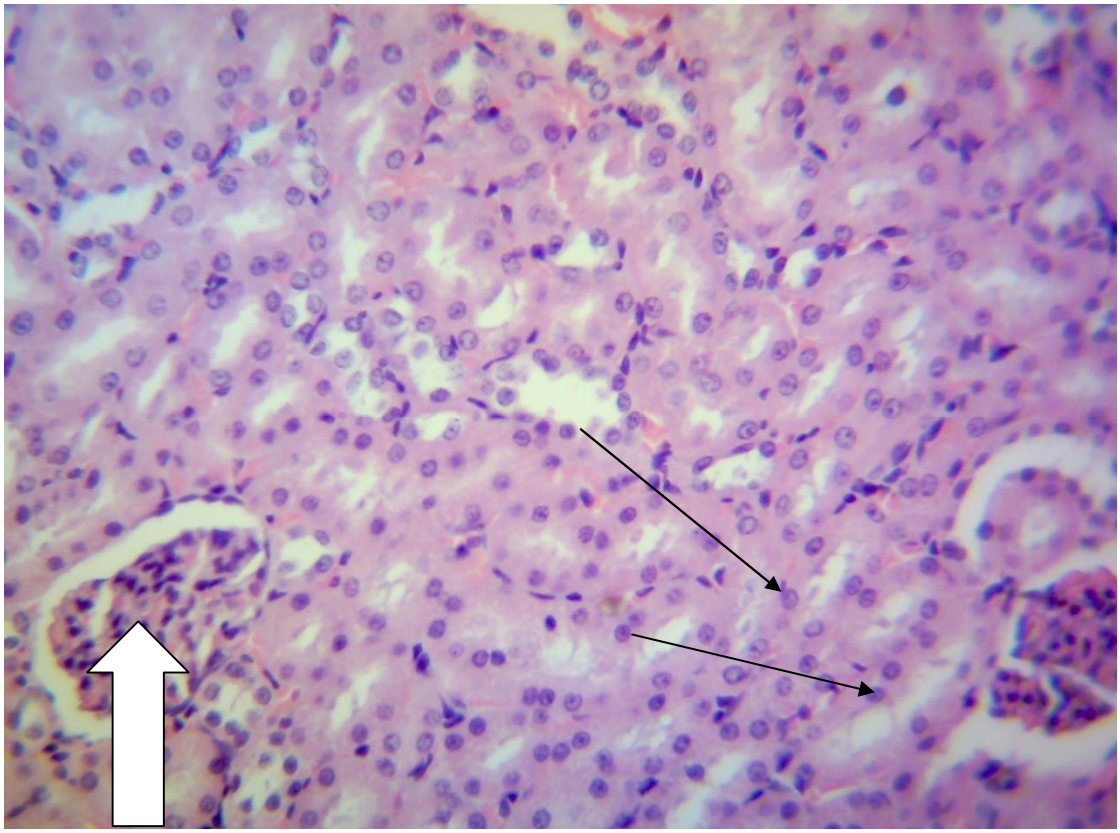

Plate 7: Kidney of normal control rats (Group 6) showing glomerulus (White arrow) and normal renal tubular epithelial cells (Black arrows) (H&E X400)

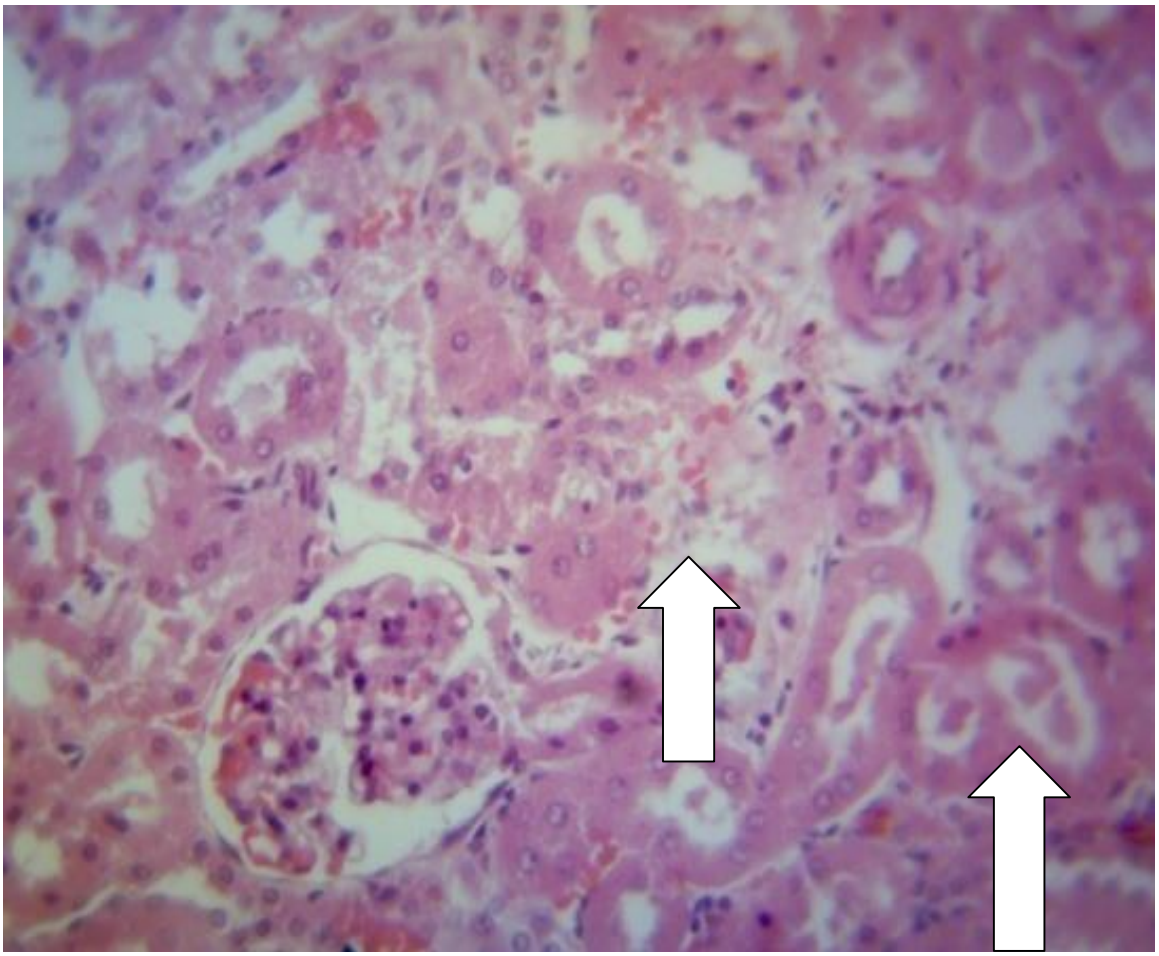

Plate 8: Kidney of rats in group 5 showing erosion of epithelial cells of the renal tubules (White arrows) (H&E X400)

Plate 9: Kidney of group1 rats (Diabetic rats treated with 62.5 mg/kg of extract) showing infiltration with mononuclear cells in the glomerulus (White arrow) and necrosis of the tubular epithelial cells (Black arrows) (H&E X400)

4.56: Kidney of group 2 rats (Diabetic rats treated with 125 mg/kg extract) showing normal tubular epithelial cells (Arrows)

The photomicrograph of the kidney nephrons shows normal epithelial cells lining the tubules. This is comparable to what is seen in the photomicrograph of the nephrons of normal contro rats (**Plate 10**)

4.57: Kidney of group 3 rats (Diabetic rats treated with 250 mg/kg of extract) showing glomerulus (White arrow) and mild necrosis of renal tubular epithelial cells (Blackarrow)

The photomicrograph shows localized areas of tubular epithelial cell degeneration and necrosis. There is also infiltration of the glomerulus by mononuclear cells (**Plate 11**).

4.58: Kidney of diabetic rats treated with 2 mg/kg glibenclamide (Group 4) showing tubular epithelial cells (Black arrows) and glomerulus (White arrow) with no observable pathologic lesions (Arrows) (Plate 12)

This photomicrograph shows kidney nephrons with normal glomerulus and normal tubular epithelial lining cells. This was comparable to the nephron photomicrogragh of the normal control rats and rats treated with 125 mg/kg of the extract.

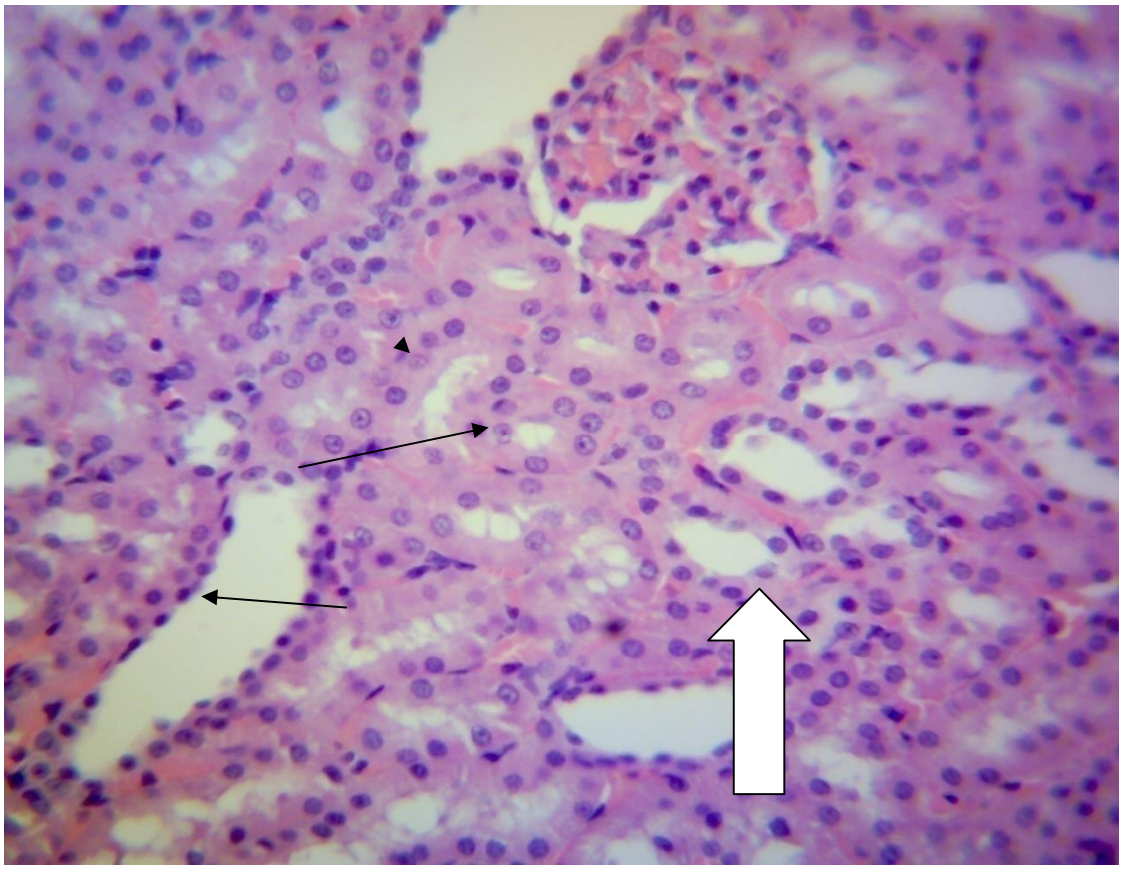

Plate 10: Kidney of group 2 rats (Diabetic rats treated with 125 mg/kg extract) showing normal tubular epithelial cells (Arrows) (H&E X400)

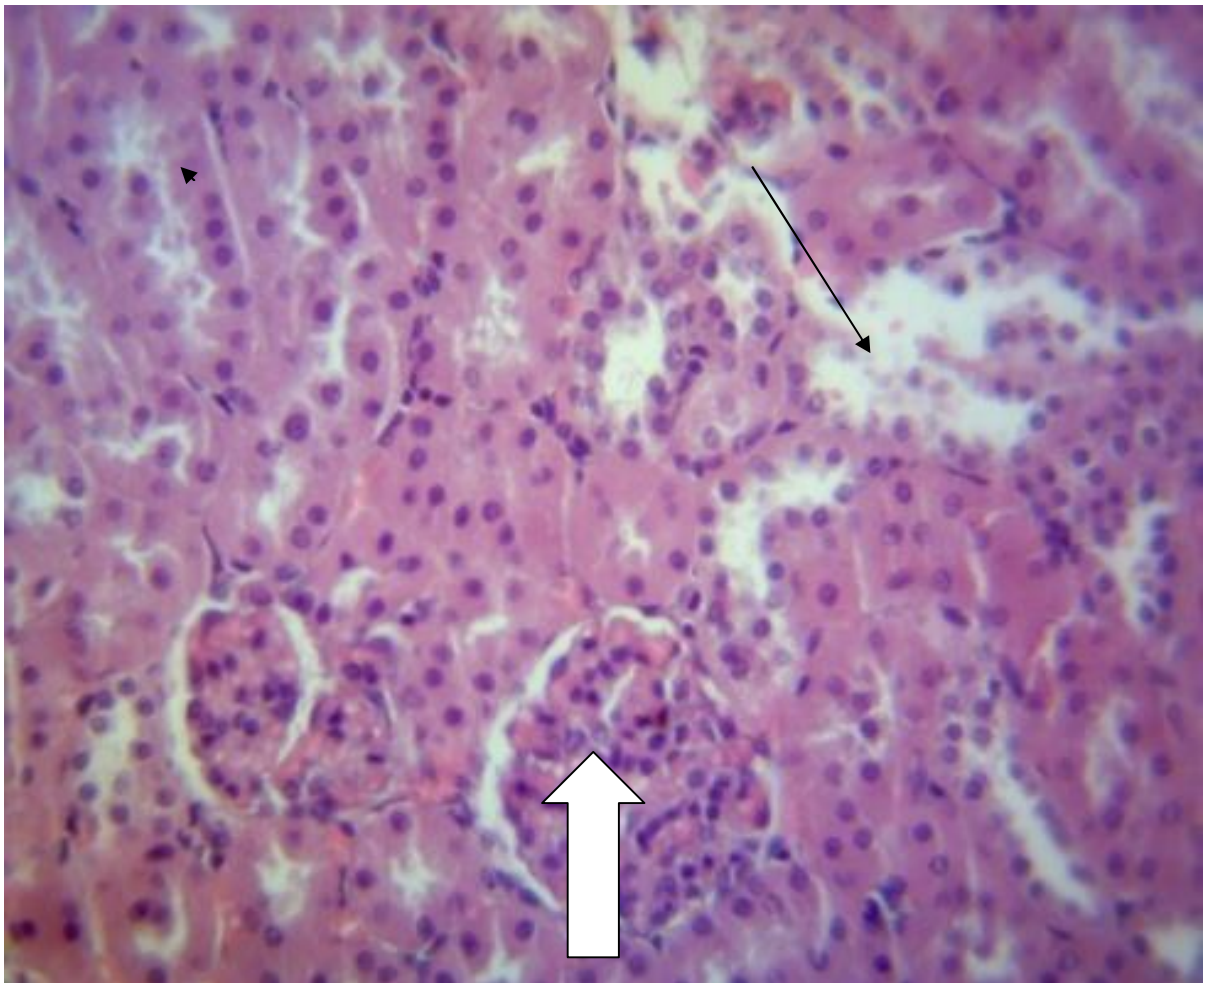

Plate 11: Kidney of group 3 rats (Diabetic rats treated with 250 mg/kg of extract) showing glomerulus (White arrow) and mild necrosis of renal tubular epithelial cells (Blackarrow) (H&E X400)

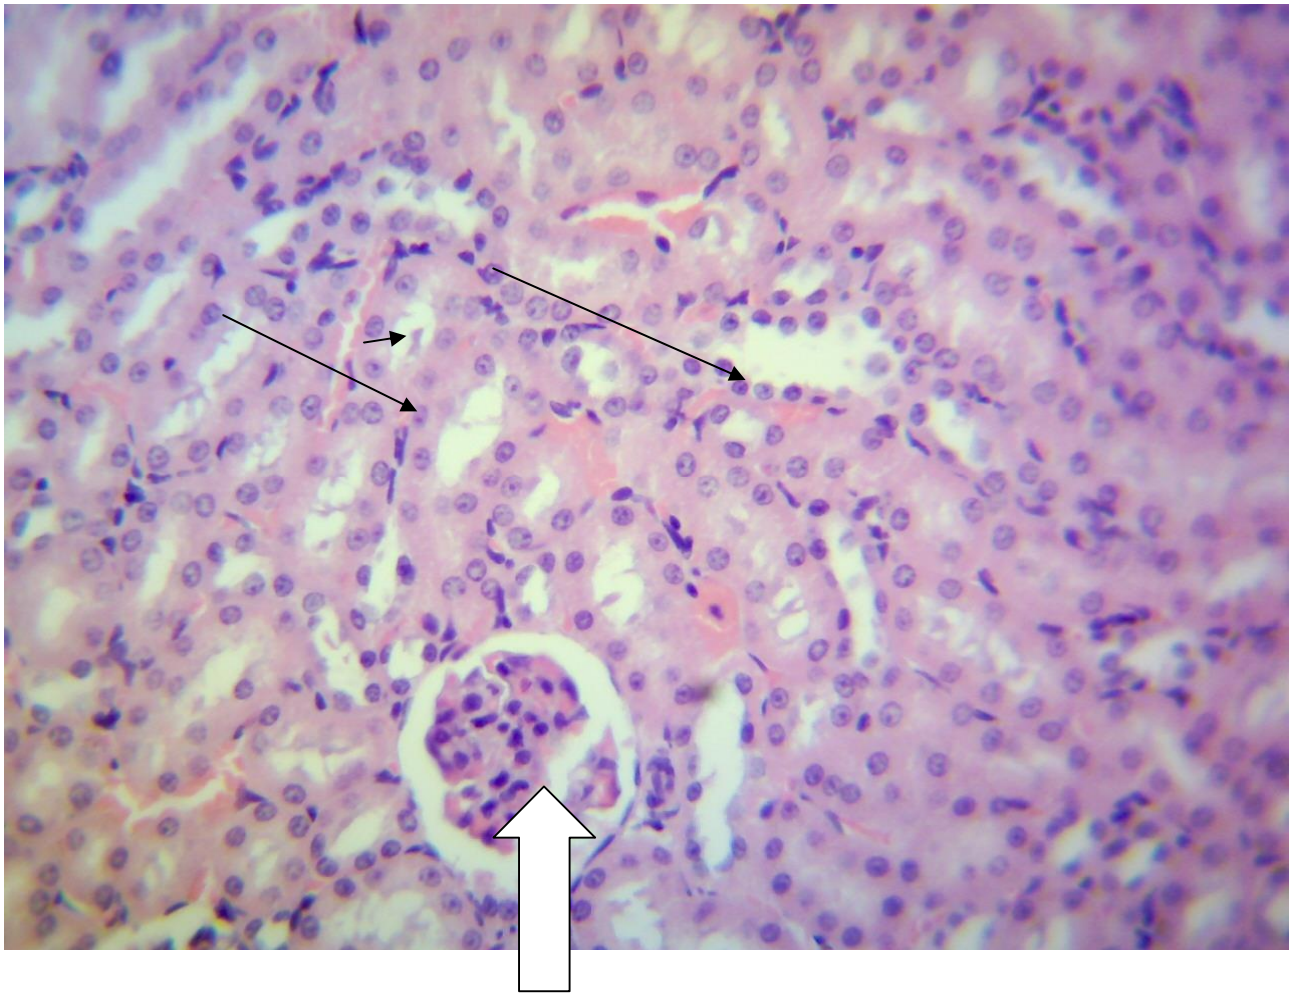

Plate 12: Kidney of diabetic rats treated with 2 mg/kg glibenclamide showing tubular epithelial cells (Black arrows) and glomerulus (White arrow) with no observable pathologic lesions (Arrows) (H&E X400)

4.59: Liver of normal control rat (Group 6) showing the central vein (White arrow) with normal arrangement of hepatocytes in cords (Black arrows)

The photomicrograph of liver shows normal liver hepatocytes arranged in cords (**Plate 13**).

4.60: Liver of diabetic untreated rats (Group 5) showing severe degeneration and necrosis of hepatocytes (White arrows) and mononuclear cells infiltration (Black arrows)

The photomicrograph of liver shows generalized degeneration and necrosisof hepatocytes with infiltration of mononuclear cells. The photomicrograph is distinctly different from that of the normal control rats (**Plate 14**).

4.61: Liver of diabetic rat treated with low dose (Group 1 rats) of extract (62.5 mg/kg) showing mild infiltration of mononuclear cells (Black arrows) and mild degeneration of hepatocytes (White arrow)

The liver photomicrograph shows hepatocytes undergoing degeneration with mild infiltration by mononuclear cells. It also shows the central vein (**Plate 15**).

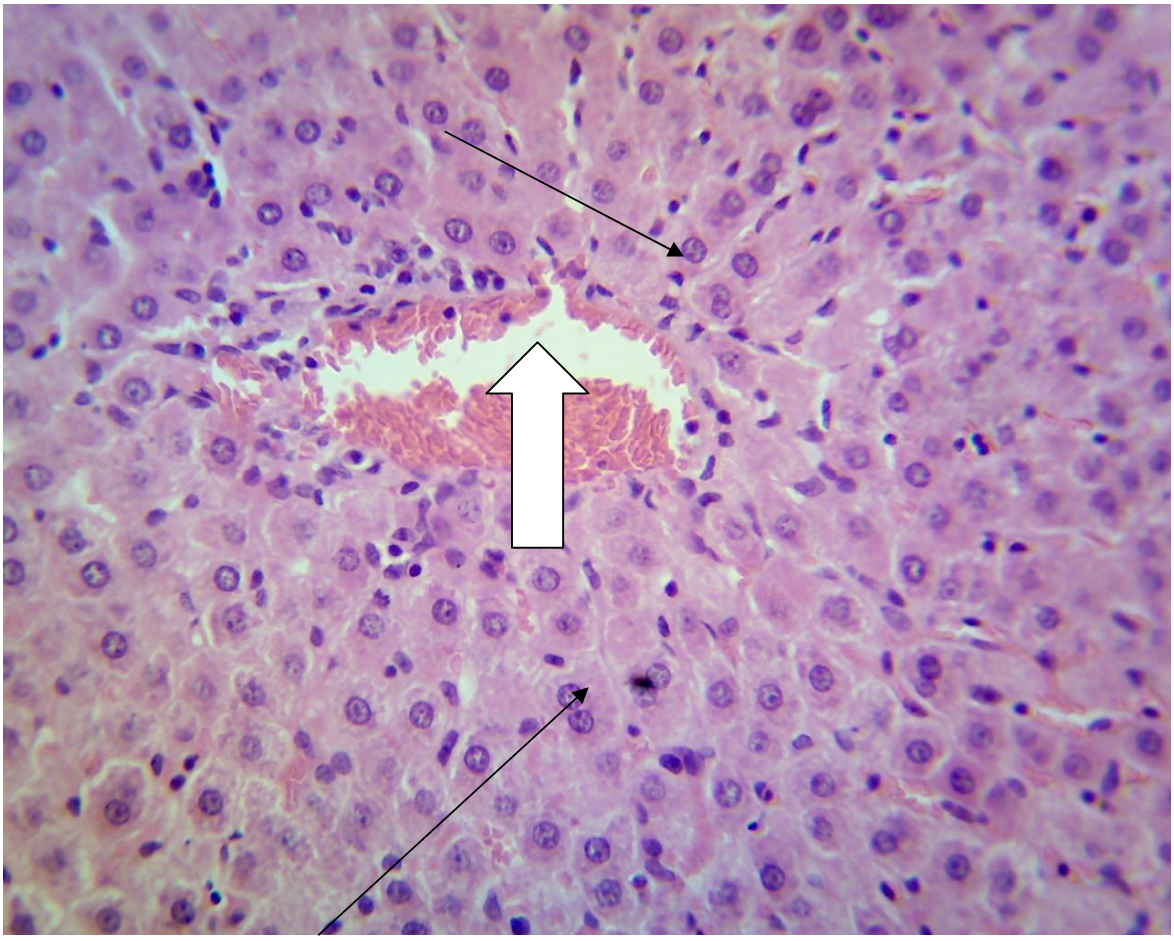

Plate 13: Liver of normal control rat showing the central vein (White arrow) with normal arrangement of hepatocytes in cords (Black arrows) (H&E X400)

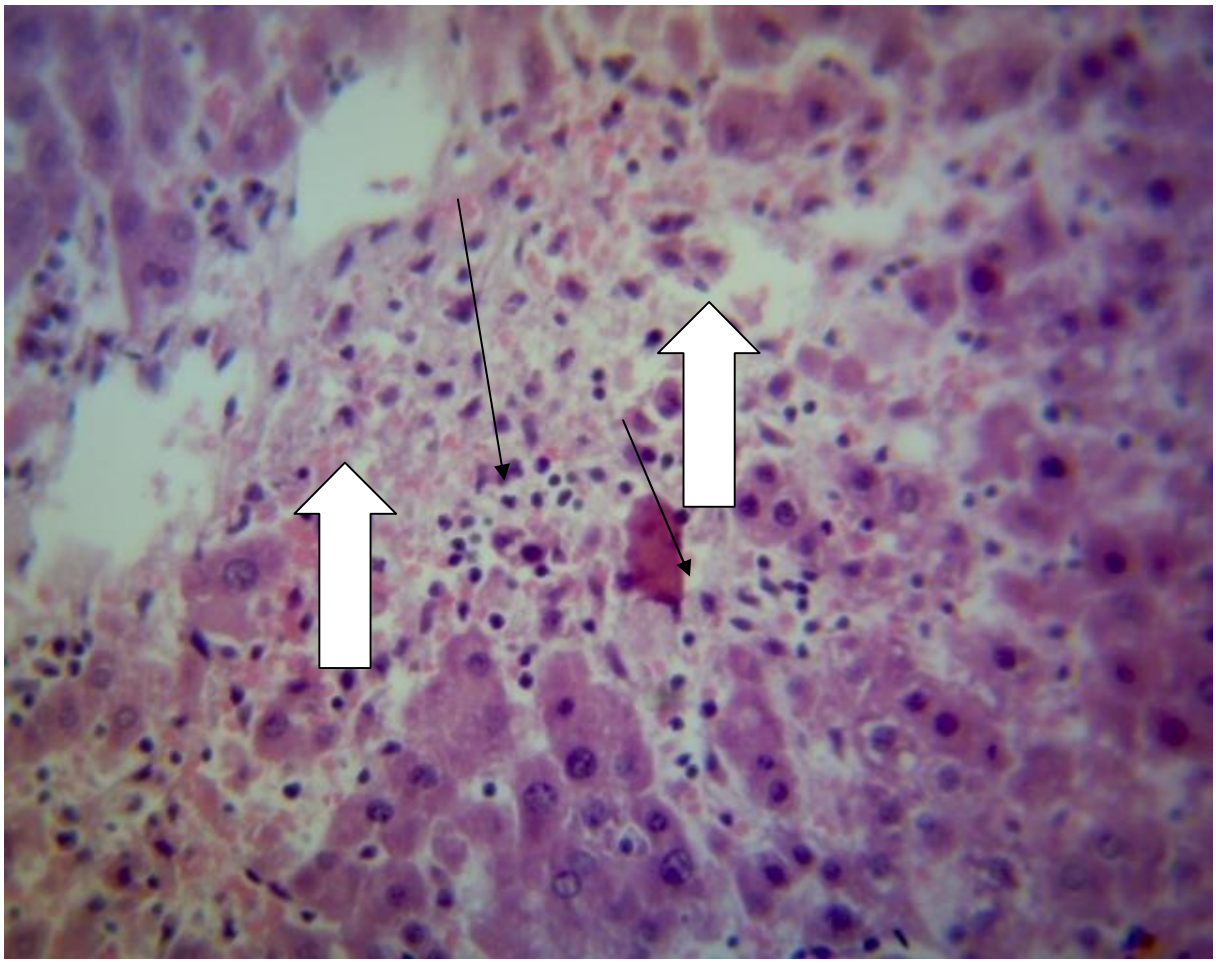

Plate 14: Liver of diabetic untreated rats (Group 5) showing severe degeneration and necrosis of hepatocytes (White arrows) and mononuclear cells infilteration (Black arrows) (H&E X400)

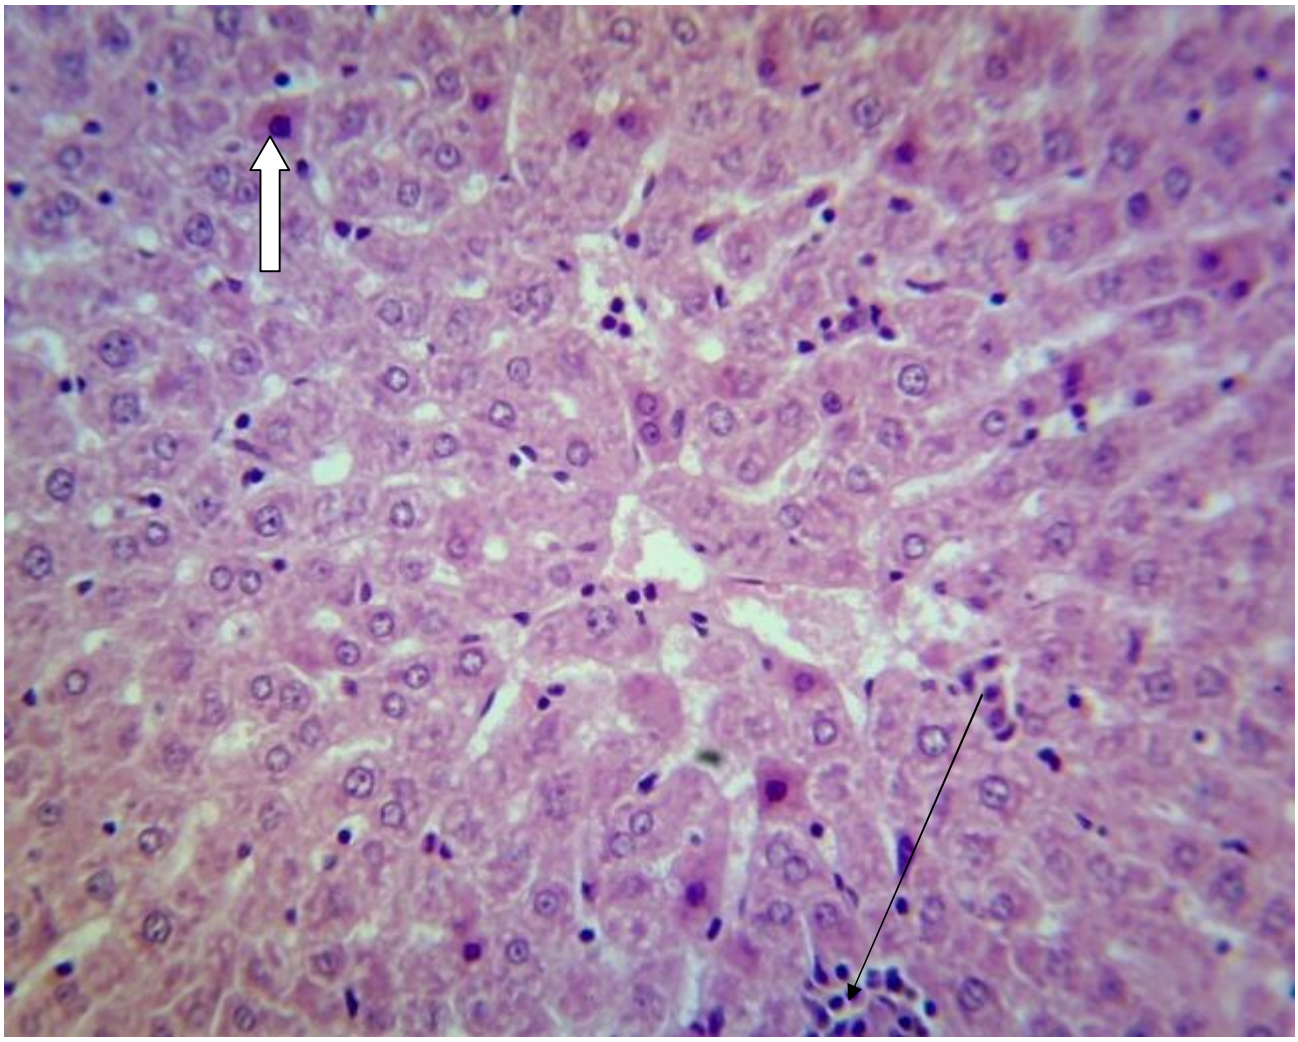

Plate 15: Liver of diabetic rat treated with low dose (Group 1 rats) of extract (62.5 mg/kg) showing mild infiltration of mononuclear cells (Black arrows) and mild degeneration of hepatocytes (White arrow) (H&E X400)

4.62: Liver of (Group 2) diabetic rat treated with middle dose (125 mg/kg of extract) showing central vein and normal hepatocyes in cords (Arrows)

This liver photomicrograph shows the central vein and normal hepatocytes arranged in cords. The photomicrograph is comparable to that seen in the normal control rats and rats treated with 2 mg/kg glibenclamide (**Plate 16**).

4.63: Liver of diabetic rat treated with high dose of extract (250 mg/kg) showing central vein (Black arrows) and hepatocytes with no obvious lesion (White arrow) This liver photomicrograph showing normal hepatocytes and central vein is comparable to that seen with the rats treated with 2 mg/kg glibenclamide, 125 mg/kg of the extract and the normal control rats **(Plate 17).**

4.64: Liver of diabetic rat treated with 2 mg/kg glibenclamide showing normal hepatocytes (Arrows).

The liver photomicragph shows normal hepatocytes and no obvious lesion. It is comparable to that of the normal control rats (**Plate 18**).

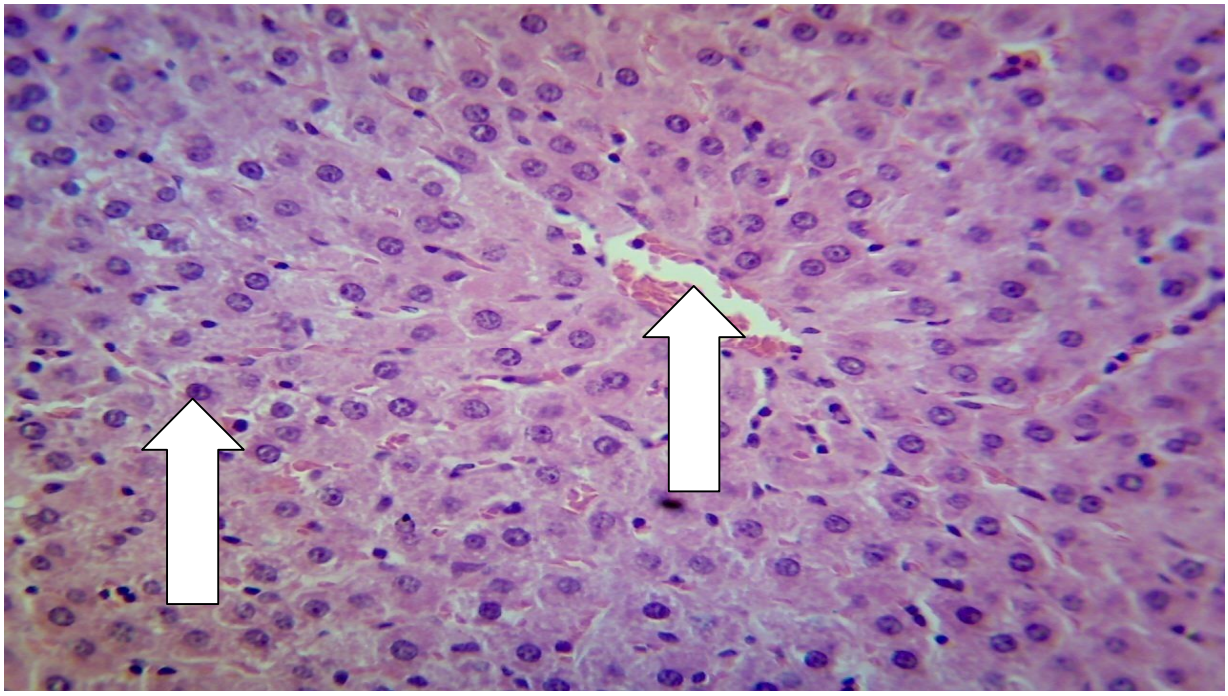

Plate 16: Liver of (Group 2) diabetic rat treated with middle dose (125 mg/kg of extract) showing central vein and normal hepatocyes in cords (Arrows) (H&E X400)

Plate 17: Liver of diabetic rat treated with high dose of extract (250 mg/kg) showing central vein (Black arrows) and hepatocytes with no obvious lesion (White arrow) (H&E X400)

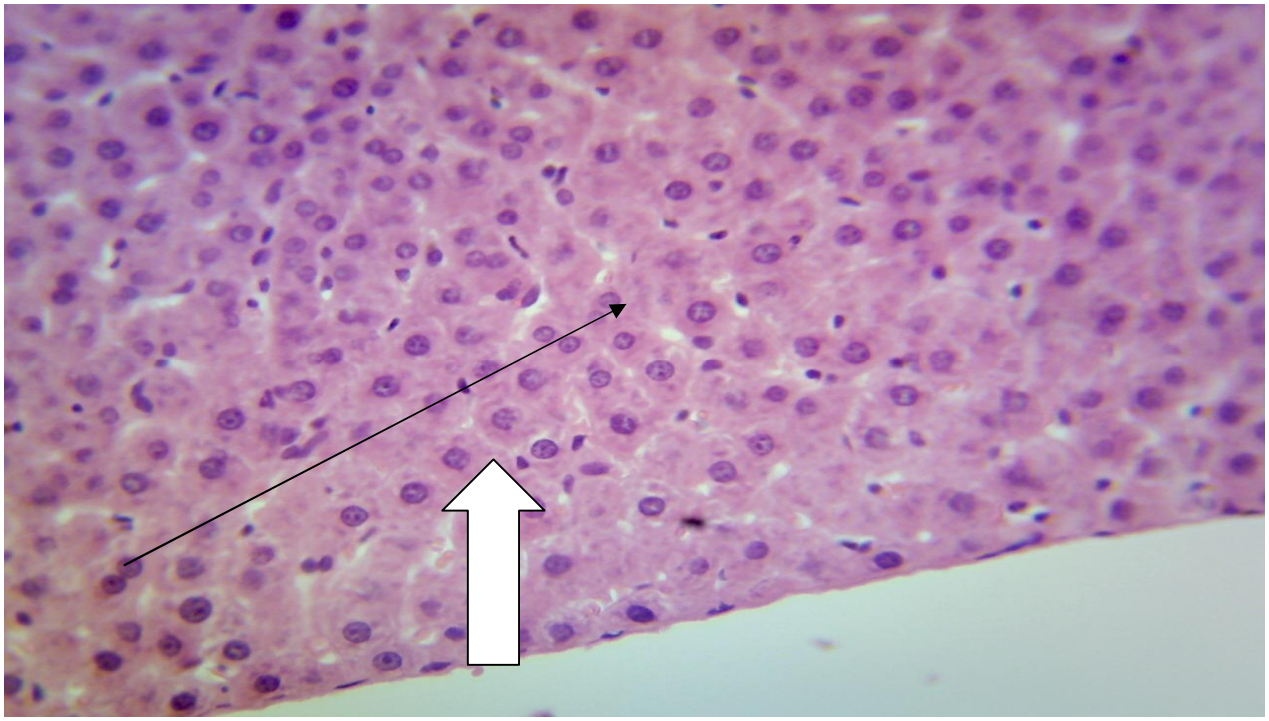

Plate 18: Liver of diabetic rat treated with 2 mg/kg glibenclamide showing normal hepatocytes (Arrows) (H&E X400)

4.65: Heart of normal control rats (Group 6) showing normal arrangement of the myocytes (arrows)

The photomicrograph shows normal spindle-shaped cardiac myocytes with no lesion seen (**Plate 19**).

4.66: Heart of diabetic untreated rats (Group 5) showing mild degeneration of myocytes (White arrows)

The photomicrograph of the heart shows necrotic myocytes and irregular arrangement of the cells. This is different from that of the normal control rats (**Plate 20**).

4.67: Heart of (Group1) diabetic rat treated with low dose (62.5 mg/kg) of the extract showing no obvious lesion

The photomicrograph of heart muscles shows cardiac myocytes in normal arrangement. This is comparable to that of the normal control rats (**Plate 21**).

4.68: Heart of (Group 2) diabetic rat treated with middle dose (125 mg/kg) of the extract with normal myocytes (Arrow) and showing no obvious lesion

The photomicrograph shows cardiac myocytes in normal arrangement with no obvious lesion. This is also comparable to that of the normal control rats (**Plate 22**).

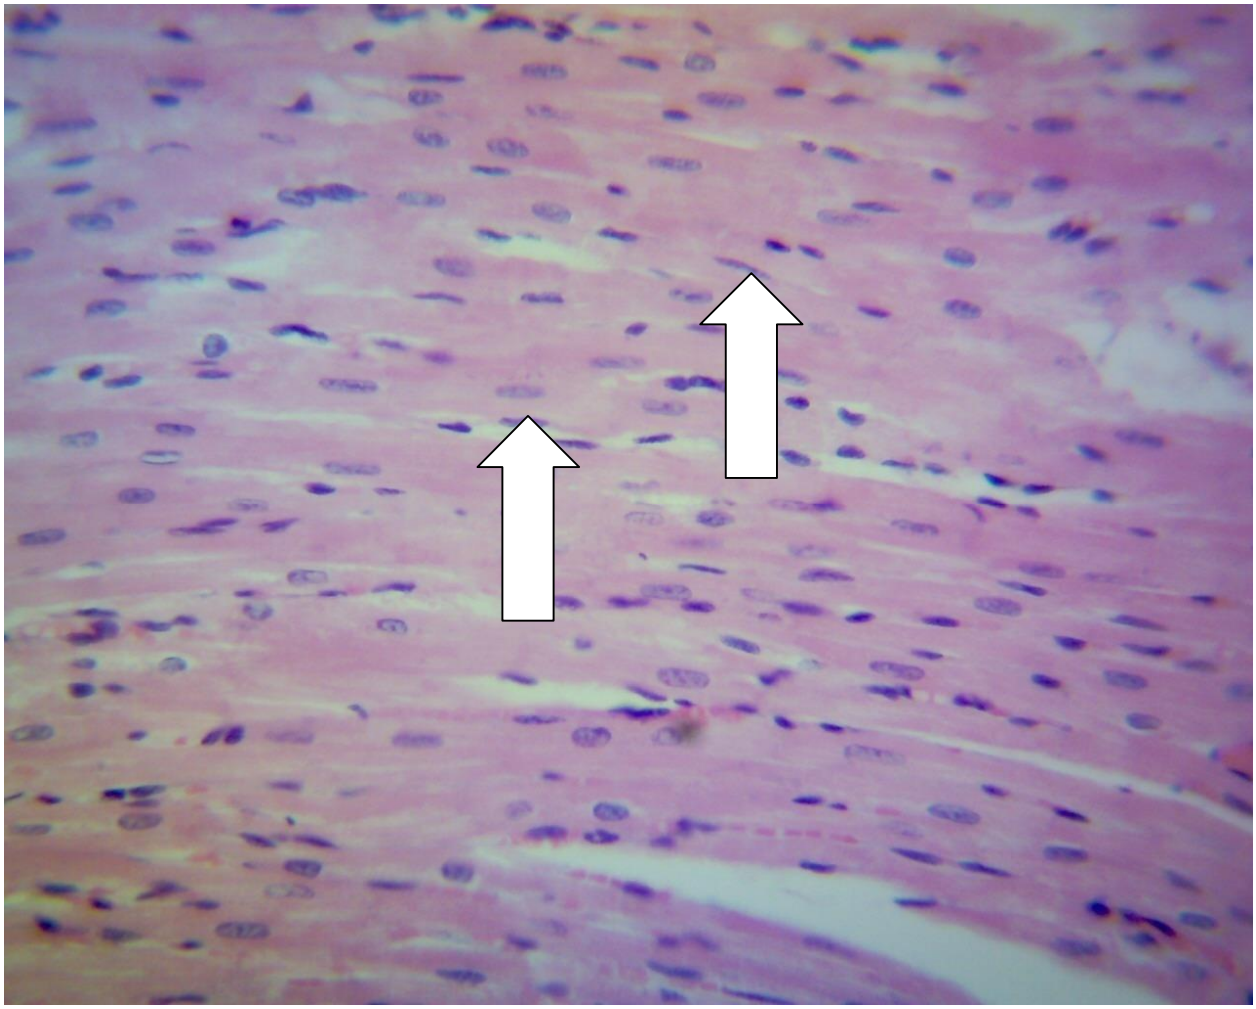

Plate 19: Heart of normal control rats (Group 6) showing normal arrangement of the myocytes (arrows) (H&E X400)

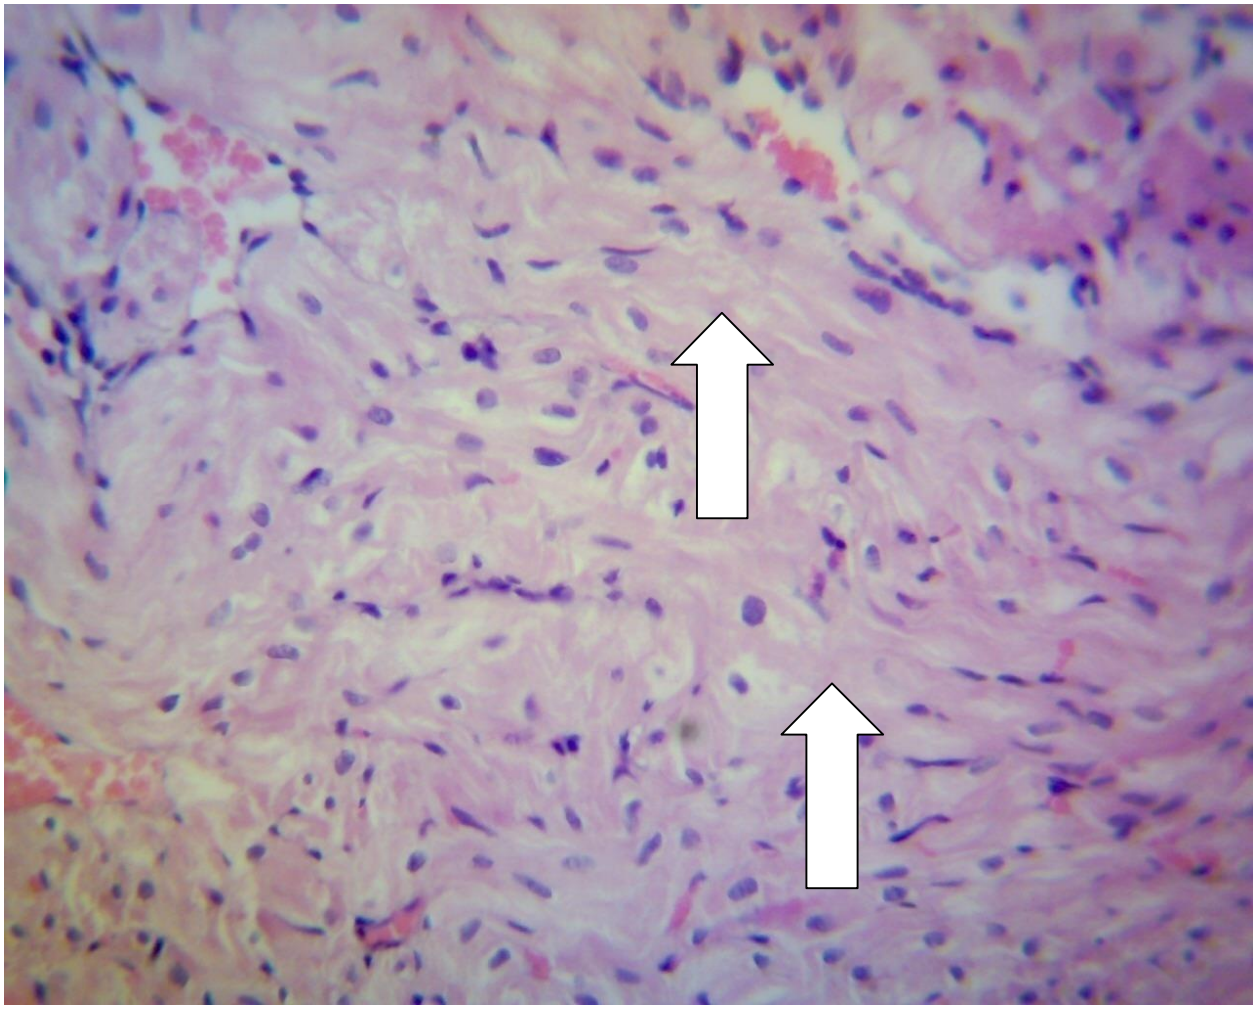

Plate 20: Heart of diabetic untreated rats (Group 5) showing mild degeneration of myocytes (White arrows) (H&E X400)

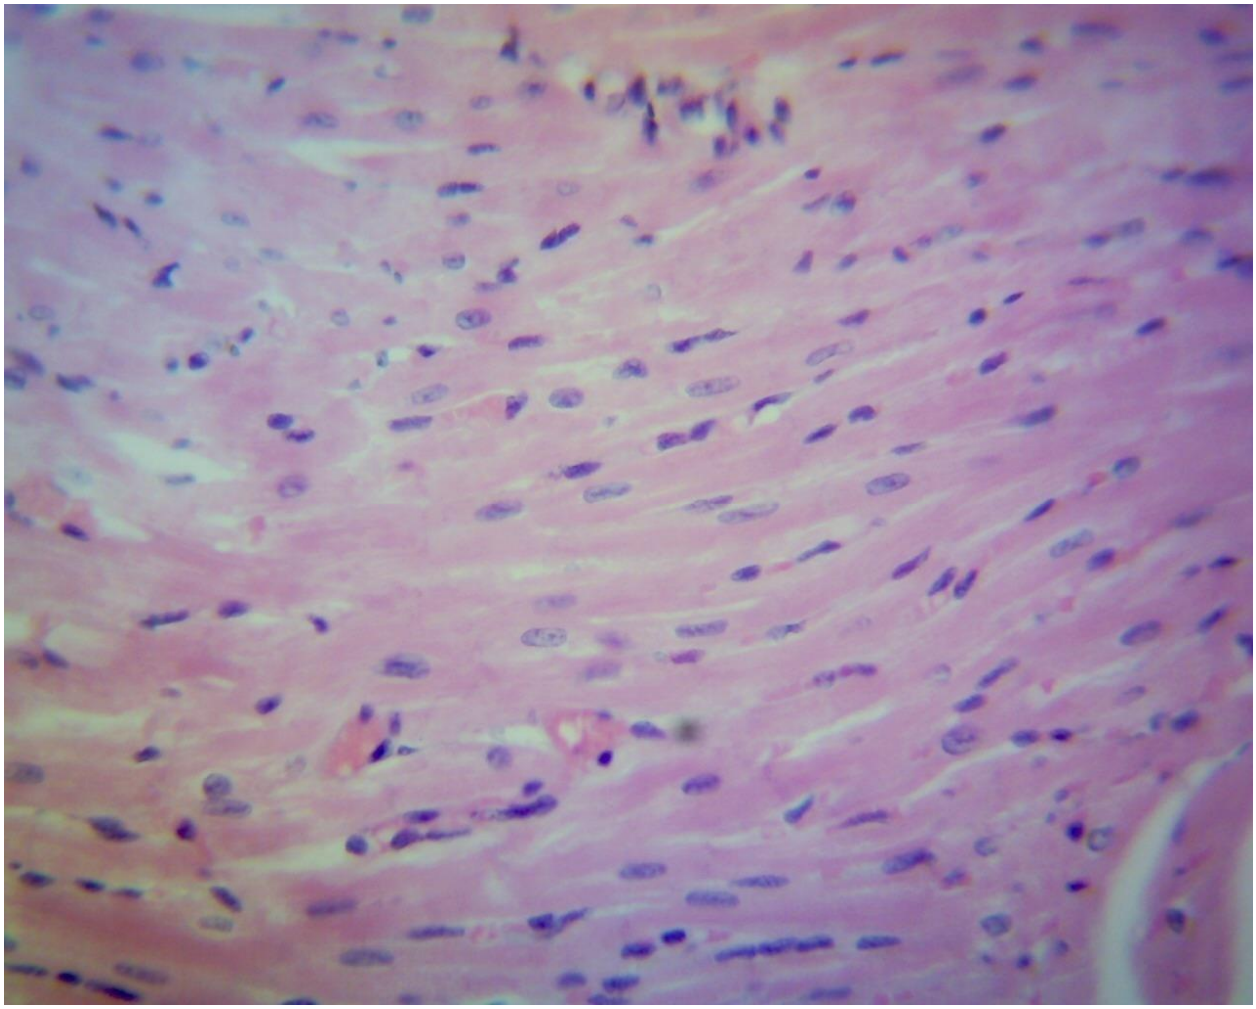

Plate 21: Heart of (Group1) diabetic rat treated with low dose (62.5 mg/kg) of the extract showing no obvious lesion (H&E X400)

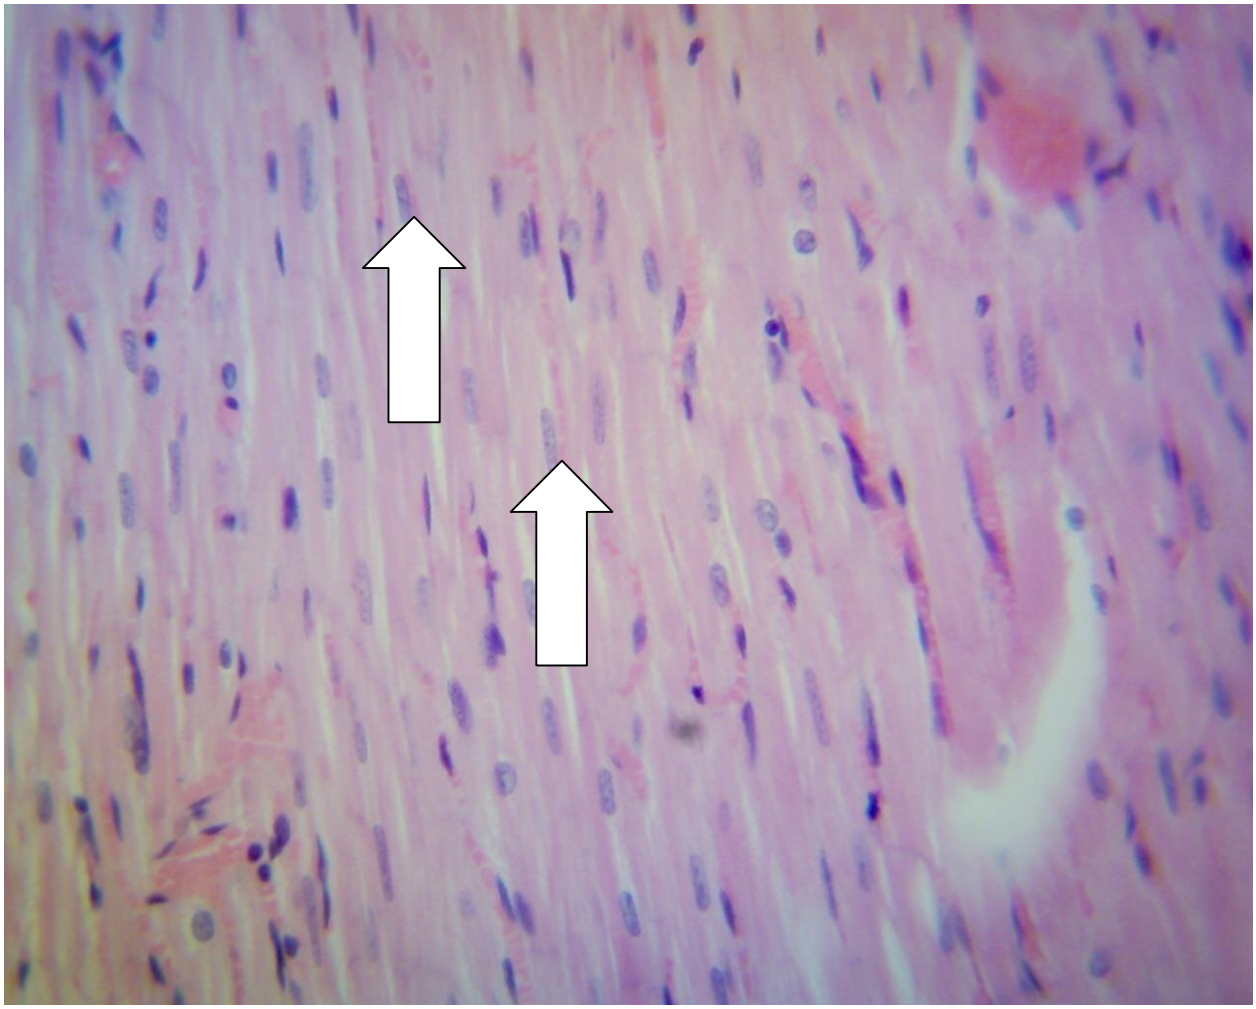

Plate 22: Heart of (Group 2) diabetic rat treated with middle dose (125 mg/kg) of the extract with normal myocytes (arrow) and showing no obvious lesion (H&E X400)

4.69: Heart of (Group 3) diabetic rat treated with high dose (250 mg/kg) of the extract showing no obvious lesion

This photomicrograph of the heart muscle cells shows normal cardiac myocytes in normal arrangement comparable to that of the normal control rats (**Plate 23**).

4.70: Heart of diabetic rat treated with 2 mg/kg of glibenclamide with normal myoctes (Arrows) and showing no obvious lesion

There is no obvious lesion seen in this photomicrograph of this cardiac photomicrograph. This is comparable to that of the normal control rats (**Plate 24**).

4.71: The purified fraction 2 (2:1) (Active compound with retention factor of 0.59)

This chromatogram of this active subfraction shows subf 2_1 with a single band, indicating purity (**Figure 12**).

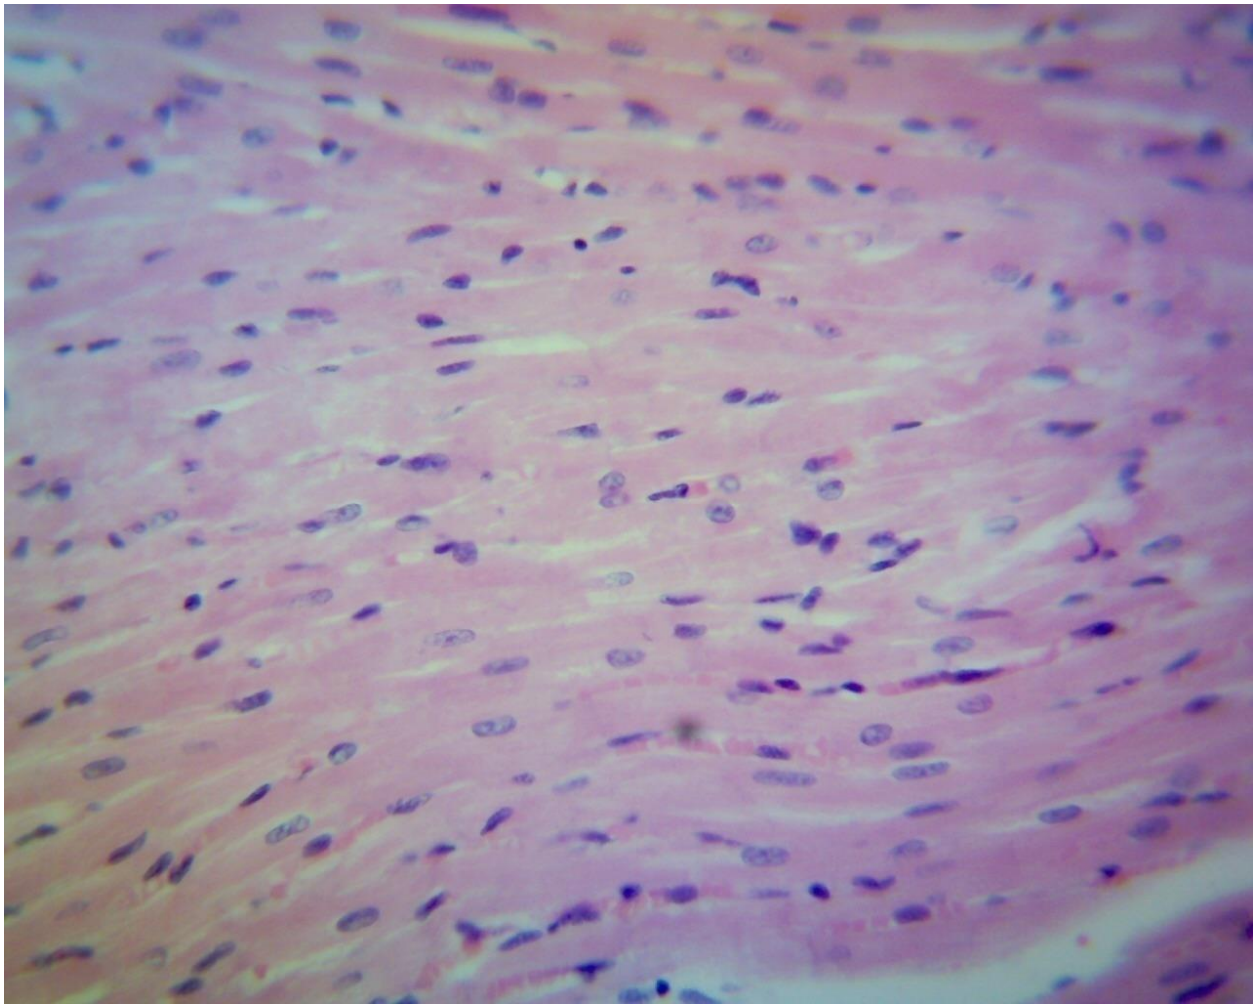

Plate 23: Heart of (Group 3) diabetic rat treated with high dose (250 mg/kg) of the extract showing no obvious lesion (H&E X400)

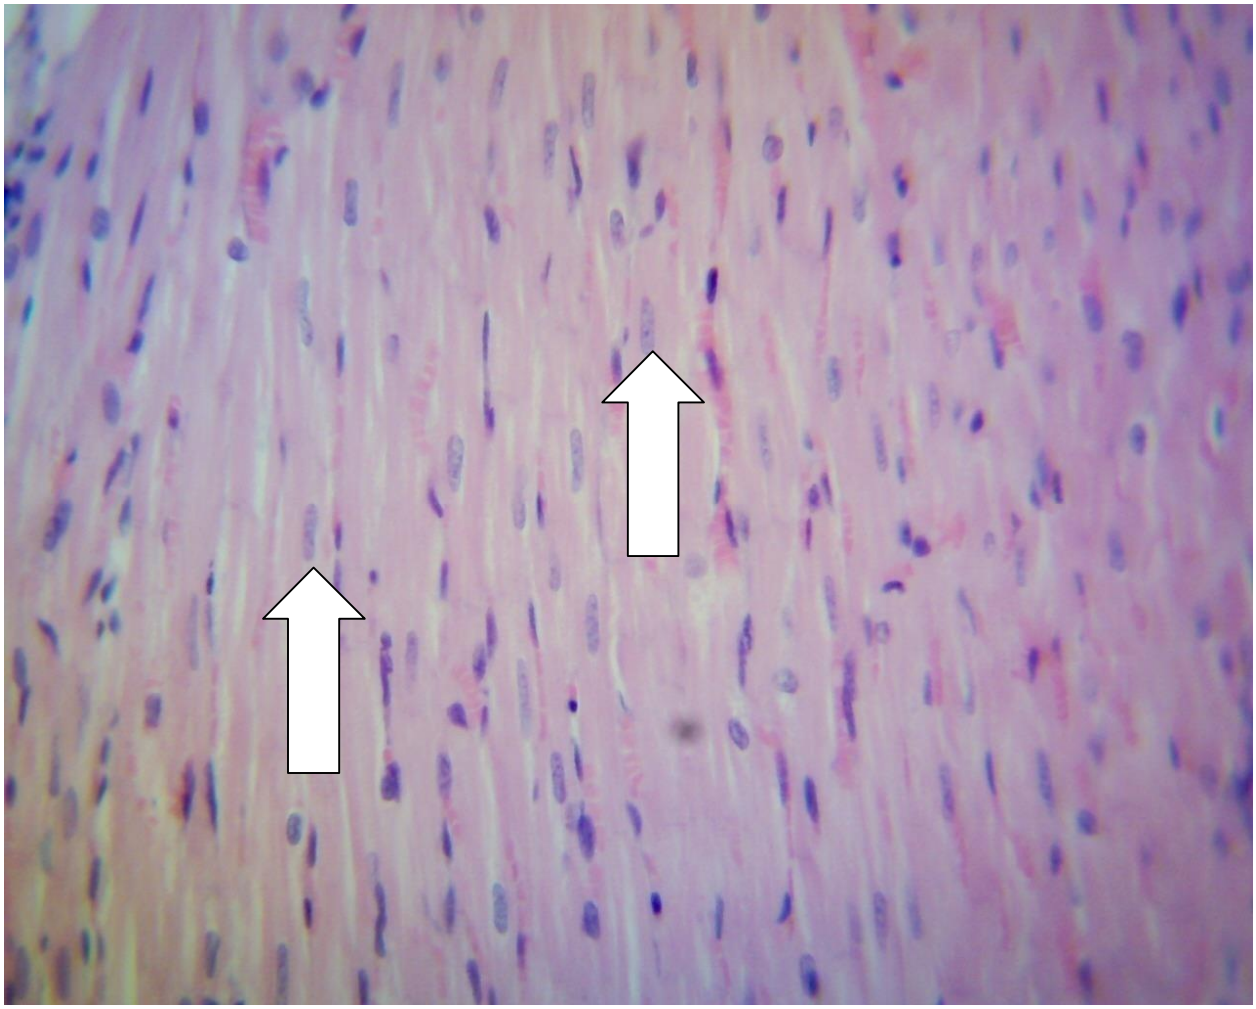

Plate 24: Heart of diabetic rat treated with 2 mg/kg of glibenclamide with normal myoctes (Arrows) and showing no obvious lesion (H&E X400)

CHAPTER FIVE

DISCUSSION AND CONCLUSION

5.1 Discussion

Diabetes mellitus is a complex and a multifarious group of disorders that disturbs the metabolism of carbohydrate, fats and protein (Kahn and Shechter 1991; Bliss, 2000) and characterized by increased fasting and postprandial blood sugar levels. It is a disorder of public health concern rapidly reaching epidemic proportion globally (Jerald *et al*., 2008). Plants have been used since time immemorial in the management of *Diabetes mellitus* (Akah *et al.,* 1998). *Cussonia arborea* is a plant used in traditional medicine for the management of *Diabetes mellitus* (Amadou *et al.,* 2008). This study intends to isolate, characterize and elucidate the active hypoglycemic principle in *C arborea* in addition to evaluating its safety, antioxidant potentials and possible haematobiochemical effects using alloxan-induced diabetic rats.

The acute toxicity study results showed that the methanol root bark extract of *C. arborea* did not produce any sign of toxicity even at the highest dose of 5000 mg/kg body weight (bw) 48 h post administration (Table 10). The low toxicity effect of medicinal plants have earlier been described by Fabricant and Farnswort (2001) who reported that medicinal plants have been documented to be safer on their long term use by humans. Phytochemical evaluation of *C. arborea* root bark extract revealed the presence of saponins, glycosides, alkaloids tannins, flavonoids and terpenes (Table 11). Researchers have reported different phytochemical compounds in medicinal plants (Tapondjou *et al.*, 2003). There is dearth of information on the phytochemical constituents of *C. arborea*. In their earlier studies Tapondjou *et al.,* (2003) and Dovgii *et al.,* (2005) reported the presence of saponins from *Cussonia bancoensis* and glycoside from *Cussonia paniculata* respectively.

The Ferric reducing antioxidant power assay was used to evaluate the antioxidant potential of *C. arborea*. Principally, FRAP assay treats the antioxidants in the sample as reductant in a redox-linked colometric reaction (Guo *et al.,* 2003). FRAP assay measures the reducing potential of an antioxidant to react on ferric tripyridyltriazine (Fe^{3+}-TPTZ) complex and produce blue colour of ferrous form (Benzie and Strain, 1999) which can be detected at 593nm. The antioxidant compounds which act as reducing agents exert their effect by donating hydrogen atom to ferric complex and thus break the radical chain reaction. The higher the absorbance, the higher the antioxidant activity which is indicated by the high FRAP value.

The result of the FRAP assay showed concentration-dependent activity. Increase in concentration of the extract resulted in increase in the absorbance of the sample. The highest FRAP value (1.5µm) of *C. arborea* was obtained at the concentration of 400 µg/ml (Figure 4). This value was statistically comparable to the FRAP value of ascorbic acid which was 2 µm (Benzie and Strain, 1999).

DPPH is a commercial oxidizing radical which can be reduced by antioxidants. In this assay, the violet colour of DPPH was reduced to pale yellow colour due to the abstraction of hydrogen atom from it. The result indicated a concentration-related antioxidant activity with the optimum of 74% for the extract and 92% for ascorbic acid (standard) at concentration of 400 µg/ml (Figure 5). The more antioxidant activity in the extract the more DPPH reduction occurred (Mohammed *et al.*, 2009). High reduction of DPPH is related to the high scavenging activity performed by any particular sample (Blois, 1958). The antioxidant property of the extract could be attributed to its phytochemical constituents such as glycosides, flavonoids, terpenes and saponins. A researcher had reported the antioxidant properties of saponin, flavonoids and terpenes (Rordrigues *et al,* 2005).

The single intraperitoneal injection of alloxan monohydrate at the dose of 160 mg/kg body weight resulted in a significant ($p<0.05$) elevation of the fasting blood glucose (FBG) levels of the rats in both the acute and chronic antidiabetic studies (Tables 12 and 14). Alloxan monohydrate and its reduced product, dialuric acid establishes a redox cycle with the formation of superoxide radicals (Szukudelski, 2001). These radicals undergo dismutation to hydrogen peroxide with a simultaneous massive increase in cytosolic calcium ion concentration which causes rapid destruction of pancreatic beta cells of the islets of langerhans resulting in a decrease in endogenous insulin secretion and attendant elevation of the blood glucose levels (Akuodor *et al.,* 2014). During this study, rats with elevated glucose levels of Ó126 mg/dl (7 mMol/L) were considered diabetic (WHO, 1980). The results of both the acute and chronic antidiabetic studies indicated that treatment of the diabetic rats with 250 mg/kg (for acute study) and 125 mg/kg (for chronic study), significantly ($p<0.05$) reduced the elevated glucose levels 6 hours and 14 days post extract administration respectively (Tables 12 and 14). The reductions achieved by the extract at these doses were comparable to that achieved by 2 mg/kg of glibenclamide, a known anti-diabetic drug. The result is in agreement with our earlier study (Aba *et al.,* 2014) with the methanol stem bark extract of *C. arborea* which demonstrated antihyperglycaemia. Other researchers (Khazraji *et al.,* 1993**;** Lim *et al*., 2009; Liu *et al*., 2005) have also demonstrated hypoglycaemic potentials of root barks of different plants.

The results of the oral glucose tolerance test indicate that after challenging the rats with 2000 mg/kg of glucose, the blood glucose levels of the rats increased significantly (Table 13). It is a well known phenomenon that the blood glucose level increases after a meal (postprandial hyperglycemia). Pretreatment of the rats with *C. arborea* extract (250 mg/kg) showed a significant reduction of the elevated blood glucose levels compared to the distilled water

pretreated rats (Table 13). This goes a long way to confirm the antihyperglycemic properties of *C.arborea* because oral glucose tolerance measures the ability to metabolize glucose (Luzi, 1998). *C. arborea* extract caused the most significant ($p<0.05$) reduction of elevated glucose levels in the glucose-challenged rats at the dose of 250 mg/kg, 180 min post treatment. The decreases or reductions in the glucose levels of rats treated with hypoglycaemic plants in oral glucose tolerance test could be attributed to lowered intestinal glucose absorption, inhibition of renal glucose reabsorption, improved tissue glucose uptake or even gluconeogenesis inhibition which is highly activated by 18 hours fasting before glucose load (Oliveira *et al.,* 2008).

The glycosylated haemoglobin (HbA_{1c}) values of the diabetic untreated rats were significantly ($p<0.05$) higher than that of the normal control rats. However, all treatment (extract and glibenclamide) groups recorded significantly ($p<0.05$) lower HbA_{1c} value at the end of the experiments (Figure 6). Group 2, which was treated with 125 mg/kg of the extract, demonstrated the highest ameliorative effects with regards to glycosylation of haemoglobin. Glycosylated haemoglobin is a measurement that reflects both fasting and postprandial glucose concentrations over a 3-month period (Diana *et al.,* 2010). Reductions in the values of HbA_{1c} by the treated groups indicate the hypoglycaemic effect of the extracts. The result is in agreement with the findings of Anand *et al*.,(2007) and Yu *et al*., (2006) who reported the ameliorating effect of *Brassica nigra and Astragalus membranaceus* (hypoglycaemic plants) respectively on glycosylation of hemoglobin in diabetic rats. Oral hypoglycaemic agents such as glibenclamide have also been reported to lower HbA_{1c} levels of diabetic rats (Diana *et al.,* 2010).

Assesement of serum liver enzymes in alloxan-induced diabetic rats treated with graded doses of *C. arborea* root bark extract for 84 days revealed significant ($p<0.05$) decreases in the activities of aspartate aminotransferase (AST) and alanine aminotransferase (ALT) of the treatment group compared to the diabetic untreated group (Tables 17 and 18). This result is in agreement with the reports of Kadarian *et al.*, (2002). They observed that *Achyrocline satureioides*-treated diabetic rats, at the dose of 300 mg/kg, inhibited the increase of liver AST and ALT. Serum liver enzymes are biochemical parameters usually evaluated to ascertain any effects on the liver (Yusuf *et al.,* 2012). Increases in the activities of AST and ALT are associated with liver injury by drugs or any other hepatotoxin (Ramaiah, 2011). However , ALT is more specific to liver and it is thus a better parameter for evaluating liver injury while serum AST may also be associated with diseases of organs such as heart and muscle (Ozer *et al*., 2008). The significant ($p<0.05$) increases in the activities of serum AST and ALT in the diabetic untreated rats (group 5) may be attributed to the effect of alloxan on the liver. Alloxan monohydrate is toxic to the liver affecting liver function (El Demerdash *et al.,* 2005). The damaged liver therefore leads to leakage and increased levels of liver enzymes into the blood (Navarro *et al.,* 1993). In the treatment groups (extract-treated and Glibenclamide-treated), the serum activities of AST and ALT were statistically comparable ($p>0.05$) to the normal control rats at the end of the experiment. The extract and the glibenclamide convincinly ameliorated the deleterious effect of alloxan monohydrate in the treated rats by antioxidation mechanism.

The lipid profile assay showed that the diabetic untreated rats had significantly ($p<0.05$) elevated serum levels of total cholesterol, triglyceride (TG), low density lipoprotein (LDL), and very low density lipoprotein (VLDL) with significant ($p<0.05$) reductions in serum high density lipoprotein (HDL) (Tables 19-22 and Figure 7). Ozougwu *et al.,* (2013) revealed that *Diabetes*

mellitus is associated with dyslipidaemia. A cascade of pathogenic steps resulting from insulin resistance together with dysfunction of the enzyme lipoprotein lipase (LPL) could account for most of these abnormalities (dyslipidaemia). Insulin resistance in adipocytes allows exuberant lipolysis stimulated by hormone sensitive lipase resulting in excessive free fatty acid release into the blood. This results in upregulation of apolipoprotein B. Therefore the liver produces and exports an increased amount of triglyceride-rich VLDL. In diabetes, LPL activity is blunt which accounts in part for the elevated plasma VLDL-TG and the diminished HDL as well as the relatively low LDL. Secondly, when plasma VLDL-TG is elevated, cholesterol ester transfer protein (CETP) causes TG to move to HDL and LDL and conversely causes cholesterol ester to move from HDL and LDL to VLDL-TG. Hence diabetics with high plasma VLDL conconmittantly have low plasma HDL because the cholesterol ester is being transferred out of the HDL fraction, as well as a diminution in size of the LDL particle because LDL becomes TG enriched and this is converted by hepatic lipase to small dense LDL (Goldberg, 2001). Upon treatment with the extract however, the elevated total cholesterol, triglyceride, LDL, and VLDL were significantly ($p<0.05$) reduced while the levels of HDL were significantly ($p<0.05$) elevated at the end of the experiment when compared to the negative control group (Tables 19-22 and Figure. 7). This indicates that the root bark extract of *C.arborea* possesses hypolipidemic properties. These findings are in agreement with the reports of Kuma and Augusti (1989) on *Ficus bengalensis*-treated diabetic rats.

There were significant ($p<0.05$) reductions in the levels of total protein, albumin and globulin of the rats in group 5 (negative control) compared with other groups (Tables 23-25). This indicates that *Diabetes mellitus* impairs the synthetic function of the liver which may be attributed to the damage caused by alloxan monohydrate used in this case for induction of diabetes. It may also

be consequent upon loss of protein (usually albumin) in urine. Proteinuria (albuminuria) is a common finding in *Diabetes mellitus* (Olsen and Mogensen, 1996). The liver plays a vital role in protein metabolism. It helps in the synthesis of plasma proteins such as albumin, fibrinogen e.t.c (Jepson *et al.* 1986; Hasselgren *et al.,* 1984). Any damage to the liver will cause aberration in the dynamics of these products.

The increase in blood urea nitrogen (BUN) and Creatinine levels observed in group 5 rats (diabetic untreated) compared to the normal control rats may be attributed to the effect of diabetes on the kidney (diabetic nephropathy) . Diabetes has been associated with impairment of kidney function. The kidney is actively involved in the development, maintenance and resolution of hyperglycemia through gluconeogenesis and glucose excretion (Marseric, 2009). The kidney is involved in the regulation of glucose via gluconeogenesis, taking up glucose from the glomerular filterate. Glucose utilization by the kidney after overnight fast accounts approximately 10% of glucose utilized by the body (Gerich, 2010). The cellular responses of the kidney to noxious incursions vary from minor biochemical abnormalities to cell death. The effects usually reported following toxic injury to the kidney reflect decreased elimination of wastes such BUN or increased creatinine levels (Braide and Anika, 2009). The BUN and creatinine are considered important biomarkers of kidney dysfunction (Mukinda and Eagles, 2010). The BUN and creatinine levels of 125 mg/kg extract-treated rats and glibenclamide-treated rats were significantly ($p<0.05$) reduced compared to the negative control group across the duration of the experiment (Figure 8 and Table 27). This may probably be as a result of mitigation of diabetes by the agents (extract and glibenclamide) resulting to a corresponding amelioration of the complication (diabetic nephropathy). The result is in agreement with the

findings of Eidi *et al*., (2005) who reported decreases in the creatinine and BUN values of *Allium sativum*-treated diabetic rats.

The negative control rats showed significantly ($p<0.05$) elevated levels of both total and unconjugated bilirubin when compared to the normal control rats (Tables 28 and 29). This observation may be consequent upon hepatocellular injuries induced by diabetes thus impairing hepatocyte function such as bilirubin conjugation. The hepatocytes are responsible for uptaking and conjugating bilirubin (Murray, 2000). Treatment of the rats with the extract (125 mg/kg) resulted in significant ($p<0.05$) reduction of the total and unconjugated bilirubin and elevation of conjugated bilirubin compared to the negative control group (Tables 28 and 29). This indicates that the extract may have hepatocurative properties. It could also be due to the antidiabetic properties of the plant.

Haematological evaluation revealed significant ($p<0.05$) reductions in the red blood cell (RBC), total haemoglobin, mean corpuscular volume (MCV), mean corpuscular haemoglobin (MCH) and packed cell volume (PCV), values of the diabetic untreated rats compared to the normal control rats (Tables 32-36 and Figure 10). These observations agree with existing literature that anaemia is a common pathophysiology associated with *Diabetes mellitus* (Akindele *et al.,* 2012). The occurrence of anaemia in *Diabetes mellitus* has been reported due to the increased non enzymatic glycosylation of RBC membrane proteins which correlates with hyperglycemia (Oyedemi *et al.,* 2011). Oxidation of these proteins and hyperglycemia in *Diabetes mellitus* causes an increase in the production of lipid peroxides that lead to haemolysis of RBCs (Arun and Ramesh, 2002). Significant ($p<0.05$) increases in the RBC, haemoglobin and PCV values of the extract-treated rats observed towards the end of the experiment (Tables 32-33 and Figure 10) indicate that the plant extract may have anti-anaemic properties. It could also be consequent

upon the antidiabetic effects of the extract which disrupted pathophysiology of anaemia. No significant ($p>0.05$) changes were observed in mean corpuscular haemoglobin concentration, basophil, eosinophil, monocyte, lymphocyte and total white blood cell counts (Tables 37-42). The reason for this observation is not very clear.

Results of oxidative stress markers showed that superoxide dismutase activities in rats treated with 125 mg/kg body weight of the extract was significantly ($p<0.05$) higher than that of the negative control but statistically comparable ($p>0.05$) to that of the normal control rats and those treated with glibenclamide (Table 43). This indicates that the extract could protect against diabetes by mopping up superoxide anions generated in the course of pathogenesis of diabetes mellitus. Superoxide dismutase has been recognized to play an important role in body defense mechanism against the deleterious effects of oxygen free radicals in biologic systems (Kakkar *et al*., 1983). It catalyses the dismutation of reaction of superoxide radical anion (O^{2-}) to hydrogen peroxide which is then catalysed to innocuous oxygen and water by glutathione peroxidase and catalase (Kakkar *et al.,* 1983). This is in agreement with the reports of Jain *et al*., (2010) that hypoglycemic plant-treated rats showed significant increases in superoxide dismutase activity when compared to the negative control group.

Malondialdehyde (MDA) values of the diabetic untreated rats (Group 5) were significantly ($p<0.05$) higher than those of the treated groups and normal control rats throughout the period of the experiment (Table 43). *Diabetes mellitus* is associated with increase in lipid peroxidation. Persistent hyperglycaemia in *Diabetes mellitus* leads to increased formation of free radicals through various mechanisms. These free radicals attack and damage lipids, proteins and nucleic acids and results in various late diabetic complications. Malondialdehyde is an end product of lipid proxidation which is an oxidative stress marker (Anit *et al.,* 2012). The rats treated with 125

mg/kg extract showed significantly lower MDA values which were comparable to that of the normal control rats. This indicates that the extract was able to ameliorate lipid peroxidation in diabetic rats. Pandar and Kar (2007) also reported such decreases in the MDA values of diabetic rats treated with hypoglycemic plants.

The reduced glutathione levels of diabetic untreated rats were significantly ($p<0.05$) lower compared to the normal control rats (Figure 11). Upon treatment with the extract, the reduced glutathione level was improved. Reduced glutathione is one of the major antioxidant constituents of the erythrocytes that play a major role in protecting against oxidative damage (Rizvi and Zaid, 2001). Its antioxidant function is related to oxidation of the thiol group of its cysteine residue with formation of disulfide (GSSG) (Rizvi and Zaid, 2001). This is in conformity with the findings of Jain *et al*., (2010), who reported a 4 times increase in the value of reduced glutathione value of *Aloe vera*-treated diabetic rats compared to the negative control.

The significantly ($p<0.05$) reduced catalase activities of the negative control (group 5) rats were significantly ($p<0.05$) increased upon treatment with the extract. The catalase activity of the extract-treated rats was statistically comparable to that of the normal control rats (Table 45). Catalase catalyses the decomposition of hydrogen peroxide to water and molecular oxygen. It is a very important enzyme in protecting the cell from oxidative damage by reactive oxygen species (ROS) (Chelikani *et al.*, 2004). The result therefore indicates that the extract could protect cells against oxidative damage which is the case in diabetes. Researchers (Pandar and Kar, 2007; Jain *et al*., 2010) have also reported increases in the catalase activities in hypoglycemic plant-treated diabetic rats.

A significant ($p<0.05$) decrease in weight of the diabetic untreated rats compared to the normal control rats was observed. This loss in weight may probably be as a result of *Diabetes mellitus*. *Diabetes mellitus* is associated with unexplained weight loss as a cardinal sign. Treatment of the rats with the extract and Glibenclamide improved weight gain. Glibenclamide has also been noted to increase weight of diabetic patients when used for treatment (Standiford, *et al*., 2014). This also implies that the extract may have benefits in improving weight gain in diabetic patients.

The histomorphologic assessment of various organs (pancreas, kidney, liver and heart) of diabetic rats showed various degrees of lesions. The pancreas of diabetic untreated rats showed severe depopulation of the islet cells of langerhans compared to the normal control rats. This probably is attributed to the effect of alloxan monohydrate in the pancreas. Alloxan causes the destruction of beta cells causing a reduction in insulin production with attendant diabetes mellitus (Szukuldeski, 2001). Treatment of diabetic rats with the extract ameliorated to a reasonable extent, the ongoing degenerative process in the cells of the islets of langerhans caused by alloxan. Fernandez-Alvarez *et al*., (2004) reported a regeneration of beta cell mass following treatment of streptozotocin-induced diabetic rats with tungstate for one month.

In the kidney, there were also various degrees of lesions ranging from mild to severe nephritis. The severe glomerular and tubular nephritis observed in the kidney of negative control rats may be consequent upon diabetes and or the effect of alloxan monohydrate in the kidney. Diabetes is the most common cause of chronic kidney failure in the developed and developing countries (Reutens *et al.,* 2008). Reutens *et al.,* (2008) also reported intercapillary glomerulonephritis among other lesions in diabetic nephropathy. The diabetic rats treated with various doses of the extract showed milder glomerulonephritic lesions.

The liver of the diabetic rats also showed severe degenerative changes in the hepatocytes. Some of the liver diseases occurring as a consequence of *Diabetes mellitus* include glycogen deposition (Stone and Van Thiel, 1985), steatohepatitis and cirrhosis (Hano, 1968). The diabetic rats treated with various doses of the extract revealed milder lesions compared with that of the diabetic untreated rats.

The cardiac myocytes of the diabetic untreated rats were severely degenerated. Diabetes increases necrosis by four fold in cardiac myocytes, nine fold in endothelial cells and six fold in fibroblasts (Frustaci *et al.,* 2000). The authors also reported that diabetes was characterized by 85-fold, 61-fold and 26-fold increases in the apoptosis of cardiac myocytes, endothelial cells and fibroblasts respectively.

Chromatographic analysis of *C. arborea* extract yielded seven different fractions (Table 15). Upon further purification and separation by bio-assay guided technique, subfraction one of fraction two (Figures 12) demonstrated hypoglycaemic potential after reducing the fasting blood glucose levels of diabetic rats from 310.00 ±5.77 to 80.00 ±0.57 mg/dl six hours post administration (Table 16). This subfraction was eluted with Hexane: Ethlyacetate in the ratio of 3:2. The active fraction (1.25 mg/kg) achieved 74% reduction of the fasting blood glucose levels of diabetic rats compared to the crude extract (125 mg/kg) which reduced the glucose levels by 73%. Thus, at a very minimal dose, the hypoglycemic potency of the active compound compares very well with that of the crude extracts.

Nuclear Magnetic Resonance (NMR) (proton and ^{13}carbon NMR) (Figures 13 and 14) was used for structural elucidation of active fraction of the extract. It was identified as an unsaturated pentacyclic triterpene, {(3ϐ)-3-hydroxyolean-12-en-28-oic acid} (Figure 15). This is an

Oleanolic acid. Triterpenes such as Oleanolic acids have been reported to possess antidiabetic activities. Oleanolic acid is a triterpenoid natural product found in a variety of plants and has been demonstrated to have a variety of biological effects. Interestingly, Oleanolic acid has been shown to have glucose-lowering properties in animal models *in vivo* (Yoshikawa and Matsuda, 2000). The mechanism by which Oleanolic acid reduces glycemia is not established. Several possibilities have been identified including effects on reducing gastric emptying (Yoshikawa and Matsuda, 2000), enhancing acetylcholine release that in turn may augment insulin release (Hsu et al., 2006) or reducing insulin resistance (Sato *et al.,* 2007). A recent study using the glucose unresponsive pancreatic beta cell line RINm5F has also suggested that Oleanolic acid may stimulate insulin secretion (Zhang *et al*., 2004). In a study by Teodoro *et al.,* (2008), Oleanolic acid significantly enhanced insulin secretion at basal and stimulatory glucose concentrations in INS-1 832/13 cells and enhanced acute glucose-stimulated insulin secretion in isolated rat islets. In the cell line the effects of Oleanolic acid on insulin secretion were comparable to that of the sulfonylurea tolbutamide at basal glucose levels and with the incretin mimetic Exendin-4 under glucose-stimulated conditions, yet neither Ca^{2+} nor cAMP rose in response to Oleanolic acid. Chronic treatment with Oleanolic acid increased total cellular insulin protein and mRNA levels. These effects may contribute to the anti-diabetic properties of this natural product. Oleanolic acid exerts beneficial effects against diabetes and metabolic syndrome. It improves insulin response, preserves functionality and survival of beta cells and protects against diabetes complications (Castellano *et al.,* 2013). Oleanolic acid may directly modulate enzymes connected to insulin biosynthesis, secretion and signaling. However, its major contribution appear to be derived from the interaction with important transduction pathways and many of its effects are consistently related to activation of the transcription factor NrF2. Doing that, Oleanolic acid induces the

expression of antioxidant enzymes and phase II response genes, blocks NF-kB and represses the polyol pathway, AGEs production and hyperlipidaemia (Castellano *et al.,* 2013).

5.2 CONCLUSION

The acute toxicity study result showed that the extract (*C arborea*) was not toxic even at the highest dose of 5000 mg/kg body weight of the extract. Phytochemical analysis of the extract revealed the presence of alkaloids, flavonoids, glycosides, saponins, tannins and terpenes. Oral glucose tolerance test in normoglycaemic rats showed that the plant extract, at t he dose of 250 mg/kg bw, reduced significantly, the blood glucose levels of the treated rats 180 min post glucose load compared to the distilled water treated rats that served as control. The extract demonstrated antihyperglycemia in alloxan-induced diabetic rats. The doses of 250 mg/kg body bw and 125 mg/kg bw of the extract showed the most significant hypoglycaemic activities in acute and chronic antidiabetic studies respectively.

The results of the chronic anti-diabetic studies indicated that the extract at the dose of 125 mg/kg reduced haemoglobin glycosylation and ameliorated the severity of lesions occasioned by *Diabetes mellitus* in different organs (pancreas, kidney, liver and heart). The study also showed that the extract demonstrated hypolipidemic properties with improvements in *in vivo* antioxidant parameters. Haematological assessment revealed significant increases in the red blood cell count, packed cell volume and total haemoglobin levels in the extract-treated rats. The results of the liver and kidney function tests indicate that the extract could protect against the damages caused by diabetes in these organs. The extract demonstrated *in vitro* antioxidant potential in ferric reducing antioxidant power (FRAP) and diphenyl picryl hydrazyl (DPPH) photometric assays. Chromatographic separation of the extract yielded seven fractions. Subfraction 1 of fraction 2

(fraction 2:1) showed the most significant hypoglycaemic activity. The hypoglycaemic activity of subfraction 2_1 at the dose of 1.25 mg/kg was 74.2 % while that of the crude extract at 125 mg/kg was 73.9 %. Spectroscopic elucidation of this active compound using ^{1}H proton and ^{13}Carbon nuclear magnetic resonance revealed a pentacylic triterpenoid, {(3ϐ)-3-hydroxyolean-12-en-28-oic acid}.

In general, the study showed that the methanol root bark extract of *C. arborea* did not only possess anti-hyperglycemic, hypolipidemic, antioxidant and anti-anemic properties but also reduced haemoglobin glycosylation and ameliorated the severe degenerative lesions in the pancreas, kidney, liver and cardiac myocytes occasioned by *Diabetes mellitus*.

RECOMMENDATION

It is recommended that further research in the form of clinical trial of the isolated compound be carried out.
